Copies data currently in flash to the block->data and sets the base address.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
<i>address</i>	Base address of the block data.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by FlashAddToBlock().

7.421.2.11 FlashOperate()

```
static blt_bool FlashOperate (
    blt_int8u cmd,
    blt_addr addr,
    blt_int16u data ) [static]
```

Prepares the flash command and executes it.

Parameters

<i>cmd</i>	Command to be launched.
<i>addr</i>	Physical address for operation.
<i>data</i>	Data to write to addr for operation.

Returns

BLT_TRUE if operation was successful, otherwise BLT_FALSE.

Referenced by FlashWriteBlock().

7.421.2.12 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.421.2.13 FlashSwitchBlock()

```
static tFlashBlockInfo * FlashSwitchBlock (
    tFlashBlockInfo * block,
    blt_addr base_addr ) [static]
```

Switches blocks by programming the current one and initializing the next.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
<i>base_addr</i>	Base address of the next block.

Returns

The pointer of the block info struct that is no being used, or a NULL pointer in case of error.

Referenced by FlashAddToBlock().

7.421.2.14 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.421.2.15 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.421.2.16 FlashWriteBlock()

```
static blt_bool FlashWriteBlock (
    tFlashBlockInfo * block ) [static]
```

Programs FLASH_WRITE_BLOCK_SIZE bytes to flash from the block->data array.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
--------------	--

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by FlashDone().

7.421.2.17 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.421.3 Variable Documentation

7.421.3.1 blockInfo

```
tFlashBlockInfo blockInfo [static]
```

Local variable with information about the flash block that is currently being operated on.

The smallest amount of flash that can be programmed is FLASH_WRITE_BLOCK_SIZE. A flash block manager is implemented in this driver and stores info in this variable. Whenever new data should be flashed, it is first added to a RAM buffer, which is part of this variable. Whenever the RAM buffer, which has the size of a flash block, is full or data needs to be written to a different block, the contents of the RAM buffer are programmed to flash. The flash block manager requires some software overhead, yet results in faster flash programming because data is first harvested, ideally until there is enough to program an entire flash block, before the flash device is actually operated on.

7.421.3.2 bootBlockInfo

```
tFlashBlockInfo bootBlockInfo [static]
```

Local variable with information about the flash boot block.

The first block of the user program holds the vector table, which on the STM32 is also the where the checksum is written to. Is it likely that the vector table is first flashed and then, at the end of the programming sequence, the checksum. This means that this flash block need to be written to twice. Normally this is not a problem with flash memory, as long as you write the same values to those bytes that are not supposed to be changed and the locations where you do write to are still in the erased 0xFF state. Unfortunately, writing twice to flash this way, does not work reliably on all micros. This is why we need to have an extra block, the bootblock, placed under the management of the block manager. This way is it possible to implement functionality so that the bootblock is only written to once at the end of the programming sequence.

7.421.3.3 flashExecCmd

```
const b1t_int8u flashExecCmd[] [static]
```

Initial value:

```
=
{
    0x36,
    0x34,
    0xce, 0x01, 0x00,
    0x1a, 0x05,
    0x86, 0x80,
    0x6a, 0x00,
    0xa7, 0xa7, 0xa7, 0xa7,
    0x0f, 0x00, 0x40, 0xfc,
    0x30,
    0x32,
    0x3d
}
```

Array with executable code for performing flash operations.

This array contains the machine code to perform the actual command on the flash device, such as program or erase. the code is compiler and location independent. This allows us to copy it to a ram buffer and execute the code from ram. This way the flash driver can be located in flash memory without running into problems when erasing/programming the same flash block that contains the flash driver. the source code for the machine code is as follows: `// launch the command FLASH->fstat = CBEIF_BIT; // wait at least 4 cycles (per AN2720) asm("nop"); asm("nop"); asm("nop"); // wait for command to complete while ((FLASH->fstat & CCIF_BIT) != CCI←F_BIT);`

Referenced by `FlashDone()`, and `FlashExecuteCommand()`.

7.421.3.4 flashLayout

```
const tFlashSector flashLayout[] [static]
```

If desired, it is possible to set `BOOT_FLASH_CUSTOM_LAYOUT_ENABLE` to `> 0` in `blt_conf.h` and then implement your own version of the `flashLayout[]` table in a source-file with the name `flash_layout.c`. This way you customize the flash memory size reserved for the bootloader, without having to modify the `flashLayout[]` table in this file directly. This file will then include `flash_layout.c` so there is no need to compile it additionally with your project.

Array wit the layout of the flash memory.

Also controls what part of the flash memory is reserved for the bootloader. If the bootloader size changes, the reserved sectors for the bootloader might need adjustment to make sure the bootloader doesn't get overwritten. This layout uses linear addresses only. For example, the first address on page 0x3F is: `0x3F * 0x4000` (page size) = `0xFC000`. Note that page 0x3F is where the bootloader also resides and it has been entered as 8 chunks of 2kb. This allows flexibility for reserving more/less space for the bootloader in case its size changes in the future.

7.422 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void [FlashInit](#) (void)
Initializes the flash driver.
- void [FlashReinit](#) (void)
Reinitializes the flash driver.
- [blt_bool](#) [FlashWrite](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- [blt_bool](#) [FlashErase](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.
- [blt_bool](#) [FlashWriteChecksum](#) (void)
Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.
- [blt_bool](#) [FlashVerifyChecksum](#) (void)
Verifies the checksum, which indicates that a valid user program is present and can be started.
- [blt_bool](#) [FlashDone](#) (void)
Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.
- [blt_addr](#) [FlashGetUserProgBaseAddress](#) (void)
Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

7.422.1 Detailed Description

Bootloader flash driver header file.

7.422.2 Function Documentation

7.422.2.1 [FlashDone\(\)](#)

```
blt\_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.422.2.2 [FlashErase\(\)](#)

```
blt\_bool FlashErase (
    blt\_addr addr,
    blt\_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.422.2.3 FlashGetUserProgBaseAddress()

```
b1t_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.422.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.422.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.422.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.422.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.422.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.423.2 Function Documentation

7.423.2.1 FlashDone()

```
blt_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.423.2.2 FlashErase()

```
blt_bool FlashErase (
    blt_addr addr,
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.423.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.423.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.423.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.423.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

7.426.1 Detailed Description

Bootloader flash driver header file.

7.426.2 Function Documentation

7.426.2.1 FlashDone()

```
blt_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.426.2.2 FlashErase()

```
blt_bool FlashErase (  
    blt_addr addr,  
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.426.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.426.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.426.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.426.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.426.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.426.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.427 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void [FlashInit](#) (void)
Initializes the flash driver.
- void [FlashReinit](#) (void)
Reinitializes the flash driver.
- [blt_bool](#) [FlashWrite](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- [blt_bool](#) [FlashErase](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.
- [blt_bool](#) [FlashWriteChecksum](#) (void)
Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.
- [blt_bool](#) [FlashVerifyChecksum](#) (void)
Verifies the checksum, which indicates that a valid user program is present and can be started.
- [blt_bool](#) [FlashDone](#) (void)
Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.
- [blt_addr](#) [FlashGetUserProgBaseAddress](#) (void)
Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

7.427.1 Detailed Description

Bootloader flash driver header file.

7.427.2 Function Documentation

7.427.2.1 FlashDone()

```
blt_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.427.2.2 FlashErase()

```
blt_bool FlashErase (
    blt_addr addr,
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.427.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.427.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.427.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.427.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.427.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.427.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (  
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.431.1 Detailed Description

Bootloader flash driver header file.

7.431.2 Function Documentation

7.431.2.1 [FlashDone\(\)](#)

```
blt\_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.431.2.2 [FlashErase\(\)](#)

```
blt\_bool FlashErase (
    blt\_addr addr,
    blt\_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.431.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.431.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.431.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.431.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.431.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.431.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.432 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void **FlashInit** (void)
Initializes the flash driver.
- void **FlashReinit** (void)
Reinitializes the flash driver.
- **blt_bool** **FlashWrite** (**blt_addr** addr, **blt_int32u** len, **blt_int8u** *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- **blt_bool** **FlashErase** (**blt_addr** addr, **blt_int32u** len)

7.432.1 Detailed Description

Bootloader flash driver header file.

7.432.2 Function Documentation

7.432.2.1 FlashDone()

```
blt_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.432.2.2 FlashErase()

```
blt_bool FlashErase (  
    blt_addr addr,  
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.432.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.432.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.432.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.432.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.432.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.432.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.433 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void [FlashInit](#) (void)
Initializes the flash driver.
- void [FlashReinit](#) (void)
Reinitializes the flash driver.
- [blt_bool](#) [FlashWrite](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- [blt_bool](#) [FlashErase](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.
- [blt_bool](#) [FlashWriteChecksum](#) (void)
Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.
- [blt_bool](#) [FlashVerifyChecksum](#) (void)
Verifies the checksum, which indicates that a valid user program is present and can be started.
- [blt_bool](#) [FlashDone](#) (void)
Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.
- [blt_addr](#) [FlashGetUserProgBaseAddress](#) (void)
Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

7.433.1 Detailed Description

Bootloader flash driver header file.

7.433.2 Function Documentation

7.433.2.1 FlashDone()

```
blt_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.433.2.2 FlashErase()

```
blt_bool FlashErase (
    blt_addr addr,
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.433.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.433.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.433.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.433.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.433.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.433.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (  
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Bootloader flash driver header file.

7.435.2 Function Documentation

7.435.2.1 FlashDone()

```
blt_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.435.2.2 FlashErase()

```
blt_bool FlashErase (  
    blt_addr addr,  
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.435.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.435.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.435.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.435.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.435.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.435.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.437.1 Detailed Description

Bootloader flash driver header file.

7.437.2 Function Documentation

7.437.2.1 `FlashDone()`

```
blt_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.437.2.2 `FlashErase()`

```
blt_bool FlashErase (
    blt_addr addr,
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.437.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.437.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.437.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.437.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.437.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.437.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.438 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void **FlashInit** (void)
Initializes the flash driver.
- void **FlashReinit** (void)
Reinitializes the flash driver.
- **blt_bool** **FlashWrite** (**blt_addr** addr, **blt_int32u** len, **blt_int8u** *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- **blt_bool** **FlashErase** (**blt_addr** addr, **blt_int32u** len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.
- **blt_bool** **FlashWriteChecksum** (void)

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

7.438.1 Detailed Description

Bootloader flash driver header file.

7.438.2 Function Documentation

7.438.2.1 FlashDone()

```
blt_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.438.2.2 FlashErase()

```
blt_bool FlashErase (  
    blt_addr addr,  
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.438.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.438.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.438.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.438.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.438.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.438.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.439 flash.h File Reference

Bootloader flash driver header file.

This graph shows which files directly or indirectly include this file:

Functions

- void [FlashInit](#) (void)
Initializes the flash driver.
- void [FlashReinit](#) (void)
Reinitializes the flash driver.
- [blt_bool](#) [FlashWrite](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- [blt_bool](#) [FlashErase](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.
- [blt_bool](#) [FlashWriteChecksum](#) (void)
Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.
- [blt_bool](#) [FlashVerifyChecksum](#) (void)
Verifies the checksum, which indicates that a valid user program is present and can be started.
- [blt_bool](#) [FlashDone](#) (void)
Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.
- [blt_addr](#) [FlashGetUserProgBaseAddress](#) (void)
Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

7.439.1 Detailed Description

Bootloader flash driver header file.

7.439.2 Function Documentation

7.439.2.1 FlashDone()

```
blt_bool FlashDone (
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.439.2.2 FlashErase()

```
blt_bool FlashErase (
    blt_addr addr,
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.439.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.439.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

7.439.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.439.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.439.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.439.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (  
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.440.1 Detailed Description

Bootloader flash driver header file.

7.440.2 Function Documentation

7.440.2.1 [FlashDone\(\)](#)

```
blt\_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

7.440.2.2 [FlashErase\(\)](#)

```
blt\_bool FlashErase (  
    blt\_addr addr,  
    blt\_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by NvmErase().

7.440.2.3 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

Referenced by NvmGetUserProgBaseAddress().

7.440.2.4 FlashInit()

```
void FlashInit (
    void )
```

Initializes the flash driver.

Returns

none.

Referenced by NvmInit().

7.440.2.5 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

Referenced by NvmReinit().

7.440.2.6 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by NvmVerifyChecksum().

7.440.2.7 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by FlashWriteChecksum(), and NvmWrite().

7.440.2.8 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (  
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by NvmDone().

7.441 flash_ecc.c File Reference

Bootloader flash driver source file for HCS12 derivatives with error correction code in flash memory, such as the HCS12Pxx. This flash memory uses a different addressing scheme than other HCS12 derivatives.

```
#include "boot.h"
```

Include dependency graph for flash_ecc.c:

Data Structures

- struct [tFlashSector](#)
Flash sector descriptor type.
- struct [tFlashBlockInfo](#)
Structure type for grouping flash block information.
- struct [tFlashRegs](#)
Structure type for the flash control registers.
- struct [tFlashPrescalerSysclockMapping](#)
Mapping table for finding the corect flash clock divider prescaler.

Macros

- #define [FLASH_INVALID_SECTOR_IDX](#) (0xff)
Value for an invalid flash sector.
- #define [FLASH_INVALID_ADDRESS](#) (0xffffffff)
Value for an invalid flash address.
- #define [FLASH_WRITE_BLOCK_SIZE](#) (512)
Standard size of a flash block for writing.
- #define [FLASH_TOTAL_SECTORS](#) (sizeof(flashLayout)/sizeof(flashLayout[0]))
Total numbers of sectors in array flashLayout[].
- #define [BOOT_FLASH_VECTOR_TABLE_CS_OFFSET](#) (0x82)
Offset into the user program's vector table where the checksum is located. Note that the value can be overridden in blt_conf.h, because the size of the vector table could vary. When changing this value, don't forget to update the location of the checksum in the user program accordingly. Otherwise the checksum verification will always fail.
- #define [FLASH_VECTOR_TABLE_SIZE](#) (0x80)
Total size of the vector table, excluding the bootloader specific checksum.
- #define [FLASH_START_ADDRESS](#) (flashLayout[0].sector_start)
Start address of the bootloader programmable flash.
- #define [FLASH_END_ADDRESS](#)
End address of the bootloader programmable flash.
- #define [FLASH_PAGE_SIZE](#) (0x4000) /* flash page size in bytes */
Size of a flash page on the HCS12.
- #define [FLASH_PAGE_OFFSET](#) (0x8000) /* physical start addr. of pages */
Physical start address of the HCS12 page window.
- #define [FLASH_PPAGE_REG](#) (*(volatile blt_int8u *) (0x0015))
PPAGE register to select a specific flash page.
- #define [FLASH_REGS_BASE_ADDRESS](#) (0x0100)
Base address of the flash related control registers.
- #define [FLASH](#) ((volatile tFlashRegs *) FLASH_REGS_BASE_ADDRESS)
Macro for accessing the flash related control registers.
- #define [FLASH_FDIV_MASK](#) (0x3f)
Bitmask for flash clock divider bits.
- #define [FLASH_FDIV_INVALID](#) (0xff)
Invalid value for the flash clock divider bits.
- #define [FLASH_CMD_MAX_PARAMS](#) (4)
Maximum number of flash command parameters.
- #define [FLASH_PHRASE_SIZE](#) (8)
A phrase is an aligned group of 4 16-bit words, so 8 bytes.
- #define [FLASH_ERASE_SECTOR_CMD](#) (0x0A)
Erase sector flash command.

- #define **FLASH_PROGRAM_PHRASE_CMD** (0x06)
Program phrase flash command.
- #define **CCIF_BIT** (0x80)
FSTAT - command complete irg flag bit.
- #define **FDIVLD_BIT** (0x80)
FCLKDIV - clock divider loaded bit.
- #define **ACCERR_BIT** (0x20)
FSTAT - flash access error flag bit.
- #define **FPVIOL_BIT** (0x10)
FSTAT - flash protection violation flag bit.

Typedefs

- typedef void(* **pFlashExeCmdFct**) (void)
Pointer type to flash command execution function.

Functions

- static **blt_bool** **FlashInitBlock** (**tFlashBlockInfo** *block, **blt_addr** address)
Copies data currently in flash to the block->data and sets the base address.
- static **tFlashBlockInfo** * **FlashSwitchBlock** (**tFlashBlockInfo** *block, **blt_addr** base_addr)
Switches blocks by programming the current one and initializing the next.
- static **blt_bool** **FlashAddToBlock** (**tFlashBlockInfo** *block, **blt_addr** address, **blt_int8u** *data, **blt_int32u** len)
Programming is done per block. This function adds data to the block that is currently collecting data to be written to flash. If the address is outside of the current block, the current block is written to flash and a new block is initialized.
- static **blt_bool** **FlashWriteBlock** (**tFlashBlockInfo** *block)
Programs FLASH_WRITE_BLOCK_SIZE bytes to flash from the block->data array.
- static **blt_int8u** **FlashGetGlobalAddrByte** (**blt_addr** addr)
Reads the byte value from the linear address.
- static **blt_int8u** **FlashGetPhysPage** (**blt_addr** addr)
Extracts the physical flash page number from a linear address.
- static **blt_int16u** **FlashGetPhysAddr** (**blt_addr** addr)
Extracts the physical address on the flash page number from a linear address.
- static void **FlashExecuteCommand** (void)
Executes the command. The actual code for the command execution is stored as location independent machine code in array flashExecCmd[]. The contents of this array are temporarily copied to RAM. This way the function can be executed from RAM avoiding problem when try to perform a flash operation on the same flash block that this driver is located on.
- static **blt_bool** **FlashOperate** (**blt_int8u** cmd, **blt_addr** addr, **blt_int16u** params[], **blt_int8u** param_count)
Prepares the flash command and executes it.
- void **FlashInit** (void)
Initializes the flash driver.
- void **FlashReinit** (void)
Reinitializes the flash driver.
- **blt_bool** **FlashWrite** (**blt_addr** addr, **blt_int32u** len, **blt_int8u** *data)
Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.
- **blt_bool** **FlashErase** (**blt_addr** addr, **blt_int32u** len)
Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

- [blt_bool FlashWriteChecksum](#) (void)
Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.
- [blt_bool FlashVerifyChecksum](#) (void)
Verifies the checksum, which indicates that a valid user program is present and can be started.
- [blt_bool FlashDone](#) (void)
Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.
- [blt_addr FlashGetUserProgBaseAddress](#) (void)
Obtains the base address of the flash memory available to the user program. This is basically the last address in the flashLayout table converted to the physical address on the last page, because this is where the address will be in.

Variables

- static const [tFlashSector flashLayout](#) []
If desired, it is possible to set `BOOT_FLASH_CUSTOM_LAYOUT_ENABLE` to `> 0` in `blt_conf.h` and then implement your own version of the `flashLayout[]` table in a source-file with the name `flash_layout.c`. This way you customize the flash memory size reserved for the bootloader, without having to modify the `flashLayout[]` table in this file directly. This file will then include `flash_layout.c` so there is no need to compile it additionally with your project.
- static const [tFlashPrescalerSysclockMapping flashFDIVlookup](#) []
Lookup table for determining the flash clock divider setting based on the system clock speed. The flash clock must be around 1MHz and is scaled down from the system clock using a prescaler value. Note that clock speeds in the table are in kHz.
- static const [blt_int8u flashExecCmd](#) []
Array with executable code for performing flash operations.
- static [tFlashBlockInfo blockInfo](#)
Local variable with information about the flash block that is currently being operated on.
- static [tFlashBlockInfo bootBlockInfo](#)
Local variable with information about the flash boot block.
- static [blt_int8u flashExecCmdRam](#) [(sizeof(flashExecCmd)/sizeof(flashExecCmd[0]))]
RAM buffer where the executable flash operation code is copied to.

7.441.1 Detailed Description

Bootloader flash driver source file for HCS12 derivatives with error correction code in flash memory, such as the HCS12Pxx. This flash memory uses a different addressing scheme than other HCS12 derivatives.

7.441.2 Function Documentation

7.441.2.1 FlashAddToBlock()

```
static blt_bool FlashAddToBlock (
    tFlashBlockInfo * block,
    blt_addr address,
    blt_int8u * data,
    blt_int32u len ) [static]
```

Programming is done per block. This function adds data to the block that is currently collecting data to be written to flash. If the address is outside of the current block, the current block is written to flash and a new block is initialized.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
<i>address</i>	Flash destination address.
<i>data</i>	Pointer to the byte array with data.
<i>len</i>	Number of bytes to add to the block.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.2.2 FlashDone()

```
blt_bool FlashDone (  
    void )
```

Finalizes the flash driver operations. There could still be data in the currently active block that needs to be flashed.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.2.3 FlashErase()

```
blt_bool FlashErase (  
    blt_addr addr,  
    blt_int32u len )
```

Erases the flash memory. Note that this function also checks that no data is erased outside the flash memory region, so the bootloader can never be erased.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.2.4 FlashExecuteCommand()

```
static void FlashExecuteCommand (  
    void ) [static]
```

Executes the command. The actual code for the command execution is stored as location independant machine code in array flashExecCmd[]. The contents of this array are temporarily copied to RAM. This way the function can be executed from RAM avoiding problem when try to perform a flash operation on the same flash block that this driver is located on.

Returns

none.

Referenced by FlashOperate().

7.441.2.5 FlashGetGlobalAddrByte()

```
static blt_int8u FlashGetGlobalAddrByte (  
    blt_addr addr ) [static]
```

Reads the byte value from the linear address.

Parameters

<i>addr</i>	Linear address.
-------------	-----------------

Returns

The byte value located at the linear address.

Referenced by FlashWriteBlock().

7.441.2.6 FlashGetPhysAddr()

```
static blt_int16u FlashGetPhysAddr (  
    blt_addr addr ) [static]
```

Extracts the physical address on the flash page number from a linear address.

Parameters

<i>addr</i>	Linear address.
-------------	-----------------

Returns

The physical address.

Referenced by FlashGetGlobalAddrByte(), FlashGetUserProgBaseAddress(), and FlashInitBlock().

7.441.2.7 FlashGetPhysPage()

```
static blt_int8u FlashGetPhysPage (  
    blt_addr addr ) [static]
```

Extracts the physical flash page number from a linear address.

Parameters

<i>addr</i>	Linear address.
-------------	-----------------

Returns

The page number.

Referenced by FlashGetGlobalAddrByte(), and FlashInitBlock().

7.441.2.8 FlashGetUserProgBaseAddress()

```
blt_addr FlashGetUserProgBaseAddress (  
    void )
```

Obtains the base address of the flash memory available to the user program. This is basically the last address in the flashLayout table converted to the physical address on the last page, because this is where the address will be in.

Obtains the base address of the flash memory available to the user program. This is basically the first address in the flashLayout table.

Returns

Base address.

7.441.2.9 FlashInit()

```
void FlashInit (  
    void )
```

Initializes the flash driver.

Returns

none.

7.441.2.10 FlashInitBlock()

```
static blt_bool FlashInitBlock (
    tFlashBlockInfo * block,
    blt_addr address ) [static]
```

Copies data currently in flash to the block->data and sets the base address.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
<i>address</i>	Base address of the block data.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by FlashAddToBlock().

7.441.2.11 FlashOperate()

```
static blt_bool FlashOperate (
    blt_int8u cmd,
    blt_addr addr,
    blt_int16u params[ ],
    blt_int8u param_count ) [static]
```

Prepares the flash command and executes it.

Parameters

<i>cmd</i>	Command to be launched.
<i>addr</i>	Global address to operate on (18-bit).
<i>params</i>	Array with additional command parameters.
<i>param_count</i>	Number of parameters in the array.

Returns

BLT_TRUE if operation was successful, otherwise BLT_FALSE.

Referenced by FlashWriteBlock().

7.441.2.12 FlashReinit()

```
void FlashReinit (
    void )
```

Reinitializes the flash driver.

Returns

none.

7.441.2.13 FlashSwitchBlock()

```
static tFlashBlockInfo * FlashSwitchBlock (
    tFlashBlockInfo * block,
    blt_addr base_addr ) [static]
```

Switches blocks by programming the current one and initializing the next.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
<i>base_addr</i>	Base address of the next block.

Returns

The pointer of the block info struct that is no being used, or a NULL pointer in case of error.

Referenced by FlashAddToBlock().

7.441.2.14 FlashVerifyChecksum()

```
blt_bool FlashVerifyChecksum (
    void )
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.2.15 FlashWrite()

```
blt_bool FlashWrite (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Writes the data to flash through a flash block manager. Note that this function also checks that no data is programmed outside the flash memory region, so the bootloader can never be overwritten.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.2.16 FlashWriteBlock()

```
static blt_bool FlashWriteBlock (  
    tFlashBlockInfo * block ) [static]
```

Programs FLASH_WRITE_BLOCK_SIZE bytes to flash from the block->data array.

Parameters

<i>block</i>	Pointer to flash block info structure to operate on.
--------------	--

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

Referenced by FlashDone().

7.441.2.17 FlashWriteChecksum()

```
blt_bool FlashWriteChecksum (  
    void )
```

Writes a checksum of the user program to non-volatile memory. This is performed once the entire user program has been programmed. Through the checksum, the bootloader can check if the programming session was completed, which indicates that a valid user programming is present and can be started.

Returns

BLT_TRUE if successful, BLT_FALSE otherwise.

7.441.3 Variable Documentation

7.441.3.1 blockInfo

```
tFlashBlockInfo blockInfo [static]
```

Local variable with information about the flash block that is currently being operated on.

The smallest amount of flash that can be programmed is FLASH_WRITE_BLOCK_SIZE. A flash block manager is implemented in this driver and stores info in this variable. Whenever new data should be flashed, it is first added to a RAM buffer, which is part of this variable. Whenever the RAM buffer, which has the size of a flash block, is full or data needs to be written to a different block, the contents of the RAM buffer are programmed to flash. The flash block manager requires some software overhead, yet results in faster flash programming because data is first harvested, ideally until there is enough to program an entire flash block, before the flash device is actually operated on.

7.441.3.2 bootBlockInfo

```
tFlashBlockInfo bootBlockInfo [static]
```

Local variable with information about the flash boot block.

The first block of the user program holds the vector table, which on the STM32 is also the where the checksum is written to. Is it likely that the vector table is first flashed and then, at the end of the programming sequence, the checksum. This means that this flash block need to be written to twice. Normally this is not a problem with flash memory, as long as you write the same values to those bytes that are not supposed to be changed and the locations where you do write to are still in the erased 0xFF state. Unfortunately, writing twice to flash this way, does not work reliably on all micros. This is why we need to have an extra block, the bootblock, placed under the management of the block manager. This way is it possible to implement functionality so that the bootblock is only written to once at the end of the programming sequence.

7.441.3.3 flashExecCmd

```
const blt_int8u flashExecCmd[] [static]
```

Initial value:

```
=
{
    0x36,
    0x34,
    0xce, 0x01, 0x00,
    0x1a, 0x06,
    0x86, 0x80,
    0x6a, 0x00,
    0xa7, 0xa7, 0xa7, 0xa7,
    0x0f, 0x00, 0x80, 0xfc,
    0x30,
    0x32,
    0x3d
}
```

Array with executable code for performing flash operations.

This array contains the machine code to perform the actual command on the flash device, such as program or erase. the code is compiler and location independent. This allows us to copy it to a ram buffer and execute the code from ram. This way the flash driver can be located in flash memory without running into problems when erasing/programming the same flash block that contains the flash driver. the source code for the machine code is as follows: // launch the command FLASH->fstat = CCIF_BIT; // wait at least 4 cycles (per AN2720) asm("nop"); asm("nop"); asm("nop"); // wait for command to complete while ((FLASH->fstat & CCIF_BIT) != CCI↵F_BIT);

Referenced by FlashDone(), and FlashExecuteCommand().

7.441.3.4 flashLayout

```
const tFlashSector flashLayout[] [static]
```

If desired, it is possible to set BOOT_FLASH_CUSTOM_LAYOUT_ENABLE to > 0 in blt_conf.h and then implement your own version of the flashLayout[] table in a source-file with the name flash_layout.c. This way you customize the flash memory size reserved for the bootloader, without having to modify the flashLayout[] table in this file directly. This file will then include flash_layout.c so there is no need to compile it additionally with your project.

Array wit the layout of the flash memory.

Also controls what part of the flash memory is reserved for the bootloader. If the bootloader size changes, the reserved sectors for the bootloader might need adjustment to make sure the bootloader doesn't get overwritten. This layout uses global addresses only. Note that the last part is where the bootloader also resides and it has been entered as 8 chunks of 2kb. This allows flexibility for reserving more/less space for the bootloader in case its size changes in the future.

    { 0x08016000, 0x02000 },
    { 0x08018000, 0x02000 },
    { 0x0801A000, 0x02000 },
    { 0x0801C000, 0x02000 },
    { 0x0801E000, 0x02000 },
}
```

Array with the layout of the flash memory.

Also controls what part of the flash memory is reserved for the bootloader. If the bootloader size changes, the reserved sectors for the bootloader might need adjustment to make sure the bootloader doesn't get overwritten.

7.455 flash_layout.c File Reference

Custom flash layout table source file.

Variables

- static const `tFlashSector flashLayout[]`
Array with the layout of the flash memory.

7.455.1 Detailed Description

Custom flash layout table source file.

7.455.2 Variable Documentation

7.455.2.1 flashLayout

```
const tFlashSector flashLayout[] [static]
```

Initial value:

```
=
{

    { 0x08004000, 0x02000 },
    { 0x08006000, 0x02000 },
    { 0x08008000, 0x02000 },
    { 0x0800A000, 0x02000 },
    { 0x0800C000, 0x02000 },
    { 0x0800E000, 0x02000 },
    { 0x08010000, 0x02000 },
    { 0x08012000, 0x02000 },
    { 0x08014000, 0x02000 },
    { 0x08016000, 0x02000 },
    { 0x08018000, 0x02000 },
    { 0x0801A000, 0x02000 },
    { 0x0801C000, 0x02000 },
    { 0x0801E000, 0x02000 },
}
```

Array wit the layout of the flash memory.

Also controls what part of the flash memory is reserved for the bootloader. If the bootloader size changes, the reserved sectors for the bootloader might need adjustment to make sure the bootloader doesn't get overwritten.

7.456 flash_layout.c File Reference

Custom flash layout table source file.

Variables

- static const `tFlashSector flashLayout []`
Array wit the layout of the flash memory.

7.456.1 Detailed Description

Custom flash layout table source file.

7.456.2 Variable Documentation

7.456.2.1 flashLayout

```
const tFlashSector flashLayout[] [static]
```

Initial value:

```
=
{

    { 0x08008000, 0x02000 },
    { 0x0800A000, 0x02000 },

Macros

- `#define BDM_DEBUGGING_ENABLED (0)`

Configuration switch to enable programming and debugging with a BDM interface.

7.546.1 Detailed Description

Generic header file.

7.546.2 Macro Definition Documentation

7.546.2.1 BDM_DEBUGGING_ENABLED

```
#define BDM_DEBUGGING_ENABLED (0)
```

Configuration switch to enable programming and debugging with a BDM interface.

To configure the program for downloading with the OpenBLT bootloader, set this value to 0. This is typically done for release versions. If support for programming and debugging with a BDM debugger interface is desired during development, then set this value to 1.

#define BDM_DEBUGGING_ENABLED (0)
```

Configuration switch to enable programming and debugging with a BDM interface.

To configure the program for downloading with the OpenBLT bootloader, set this value to 0. This is typically done for release versions. If support for programming and debugging with a BDM debugger interface is desired during development, then set this value to 1.

7.548 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
```

Include dependency graph for `_template/Boot/hooks.c`:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

- `blt_int8u NvmWriteHook (blt_addr addr, blt_int32u len, blt_int8u *data)`

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the data hasn't been written yet.

- `blt_int8u NvmEraseHook (blt_addr addr, blt_int32u len)`

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook (void)`

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook (blt_int8u resource, blt_int8u *seed)`

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.548.1 Detailed Description

Bootloader callback source file.

7.548.2 Function Documentation

7.548.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.548.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.548.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.548.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.548.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.548.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.548.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.548.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.548.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.548.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.548.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.548.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.549 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMCM0_STM32F0_Discovery_STM32F051_CubeIDE/Boot/App/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.549.1 Detailed Description

Bootloader callback source file.

7.549.2 Function Documentation

7.549.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.549.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.549.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.549.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.549.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.549.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.549.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.549.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.549.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.549.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.549.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.549.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.550 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.550.1 Detailed Description

Bootloader callback source file.

7.550.2 Function Documentation

7.550.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.550.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.550.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.550.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.550.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.550.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.550.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.550.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.550.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.550.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.550.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.550.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *`seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.551.1 Detailed Description

Bootloader callback source file.

7.551.2 Function Documentation

7.551.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.551.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.551.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.551.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.551.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.551.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.551.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.551.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.551.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.551.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.551.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.551.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.552 hooks.c File Reference

- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.552.1 Detailed Description

Bootloader callback source file.

7.552.2 Function Documentation

7.552.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.552.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.552.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.552.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.552.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.552.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.552.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.552.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.552.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.552.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.552.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.552.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.553 hooks.c File Reference

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.553.1 Detailed Description

Bootloader callback source file.

7.553.2 Function Documentation

7.553.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.553.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.553.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.553.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.553.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.553.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.553.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.553.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.553.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.553.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.553.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.553.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.554.1 Detailed Description

Bootloader callback source file.

7.554.2 Function Documentation

7.554.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.554.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.554.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.554.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.554.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.554.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.554.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.554.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.554.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.554.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.554.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.554.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.555 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMCM0_STM32F0_Nucleo_F091RC_IAR/Boot/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool](#) [BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool](#) [CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.555.1 Detailed Description

Bootloader callback source file.

7.555.2 Function Documentation

7.555.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.555.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.555.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.555.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.555.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.555.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.555.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.555.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.555.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.555.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.555.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.555.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.556 hooks.c File Reference

Bootloader callback source file.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u` *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u` *key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.556.1 Detailed Description

Bootloader callback source file.

7.556.2 Function Documentation

7.556.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.556.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.556.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.556.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.556.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.556.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.556.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.556.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.556.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.556.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.556.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.556.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.557.1 Detailed Description

Bootloader callback source file.

7.557.2 Function Documentation

7.557.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.557.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.557.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.557.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.557.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.557.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.557.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.557.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.557.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.557.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.557.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.557.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.558 hooks.c File Reference

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.558.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.558.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.558.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.558.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.558.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.558.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.558.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.558.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.558.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.559 hooks.c File Reference

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.559.1 Detailed Description

Bootloader callback source file.

7.559.2 Function Documentation

7.559.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.559.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.559.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.559.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.559.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.559.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.559.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.559.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.559.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.559.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.559.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.559.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.560.1 Detailed Description

Bootloader callback source file.

7.560.2 Function Documentation

7.560.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.560.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.560.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.560.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.560.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.560.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.560.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.560.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.560.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.560.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.560.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.560.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.561.1 Detailed Description

Bootloader callback source file.

7.561.2 Function Documentation

7.561.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.561.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.561.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.561.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.561.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.561.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.561.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.561.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.561.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.561.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.561.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.561.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *`seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.562.1 Detailed Description

Bootloader callback source file.

7.562.2 Function Documentation

7.562.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.562.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.562.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.562.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.562.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.562.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.562.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.562.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.562.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.562.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.562.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.562.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.563 hooks.c File Reference

Bootloader callback source file.

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook (blt_int8u resource, blt_int8u *seed)`

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.563.1 Detailed Description

Bootloader callback source file.

7.563.2 Function Documentation

7.563.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.563.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.563.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.563.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.563.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.563.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.563.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.563.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.563.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.563.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.563.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

Referenced by UsbFree(), and UsbInit().

7.563.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

Referenced by UsbBulkRxHandler().

7.563.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

Referenced by UsbBulkRxHandler().

7.563.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.563.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (  
    blt_int8u resource,  
    blt_int8u * key,  
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.564 hooks.c File Reference

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.564.1 Detailed Description

Bootloader callback source file.

7.564.2 Function Documentation

7.564.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.564.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.564.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.564.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.564.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.564.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.564.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.564.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.564.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.564.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.564.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.564.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.564.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.564.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.564.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.565.1 Detailed Description

Bootloader callback source file.

7.565.2 Function Documentation

7.565.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.565.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.565.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.565.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.565.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.565.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.565.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.565.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.565.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.565.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.565.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.565.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.565.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.565.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.565.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.566.1 Detailed Description

Bootloader callback source file.

7.566.2 Function Documentation

7.566.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.566.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

Referenced by `UsbLeaveLowPowerModeHook()`.

7.566.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.566.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.566.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.566.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.566.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.566.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.566.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.566.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.566.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.566.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.566.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.566.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.566.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.567.1 Detailed Description

Bootloader callback source file.

7.567.2 Function Documentation

7.567.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.567.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.567.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.567.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.567.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.567.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.567.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.567.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.567.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.567.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.567.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.567.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.568 hooks.c File Reference

7.568.1 Detailed Description

Bootloader callback source file.

7.568.2 Function Documentation

7.568.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.568.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.568.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.568.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.568.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.568.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.568.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.568.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.568.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.568.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.568.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.568.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.569 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "inc/hw_types.h"
#include "driverlib/gpio.h"
#include "inc/hw_memmap.h"
#include "driverlib/uartlib.h"
```

Include dependency graph for ARMC3_LM3S_EK_LM3S6965_GCC/Boot/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool](#) [BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool](#) [CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool](#) [NvmDoneHook](#) (void)
Callback that gets called at the end of the NVM programming session.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

- [blt_bool FileIsFirmwareUpdateRequestedHook](#) (void)

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

- const [blt_char](#) * [FileGetFirmwareFilenameHook](#) (void)

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- void [FileFirmwareUpdateStartedHook](#) (void)

Callback that gets called to inform the application that a firmware update from local storage just started.

- void [FileFirmwareUpdateCompletedHook](#) (void)

Callback that gets called to inform the application that a firmware update was successfully completed.

- void [FileFirmwareUpdateErrorHook](#) ([blt_int8u](#) error_code)

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

- void [FileFirmwareUpdateLogHook](#) ([blt_char](#) *info_string)

Callback that gets called each time new log information becomes available during a firmware update.

- [blt_int8u](#) [XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- [blt_int8u](#) [XcpVerifyKeyHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *key, [blt_int8u](#) len)

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const [blt_char](#) [firmwareFilename](#) [] = "/demoprogram_ek_lm3s6965.srec"

Firmware filename.

-

```
struct {
    FIL handle
    blt\_bool canUse
} logfile
```

Data structure for grouping log-file related information.

7.569.1 Detailed Description

Bootloader callback source file.

7.569.2 Function Documentation

7.569.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.569.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.569.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.569.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.569.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.569.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.569.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.569.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.569.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.569.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.569.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.569.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.569.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.569.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.569.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.569.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.569.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.569.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.569.3 Variable Documentation**7.569.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.569.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

Referenced by UsbFifoMgrRead(), UsbFifoMgrScan(), and UsbFifoMgrWrite().

7.570 hooks.c File Reference

Bootloader callback source file.

```

Data structure for grouping log-file related information.

7.570.1 Detailed Description

Bootloader callback source file.

7.570.2 Function Documentation

7.570.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.570.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.570.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.570.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.570.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.570.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.570.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (  
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.570.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (  
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.570.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.570.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.570.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.570.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.570.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (  
    blt_addr addr,  
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.570.2.14 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.570.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.570.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.570.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.570.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.570.3 Variable Documentation**7.570.3.1 canUse**

`blt_bool canUse`

Flag to indicate if the log-file can be used.

7.570.3.2 handle

`FIL handle`

FatFS handle to the log-file.

7.571 hooks.c File Reference

Bootloader callback source file.

```

    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.571.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.571.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.571.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR is the erase operation failed.

7.571.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.571.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.571.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.571.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.571.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.572 hooks.c File Reference

7.572.1 Detailed Description

Bootloader callback source file.

7.572.2 Function Documentation

7.572.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.572.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.572.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.572.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.572.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.572.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.572.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.572.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.572.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.572.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.572.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.572.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.573 hooks.c File Reference

- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.573.1 Detailed Description

Bootloader callback source file.

7.573.2 Function Documentation

7.573.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.573.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.573.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.573.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.573.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.573.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.573.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.573.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.573.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.573.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.573.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.573.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.574 hooks.c File Reference

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.574.1 Detailed Description

Bootloader callback source file.

7.574.2 Function Documentation

7.574.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.574.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.574.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.574.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.574.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.574.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.574.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.574.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.574.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.574.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.574.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.574.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.575.1 Detailed Description

Bootloader callback source file.

7.575.2 Function Documentation

7.575.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.575.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.575.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.575.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.575.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.575.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.575.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.575.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.575.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.575.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.575.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.575.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.576 hooks.c File Reference

Bootloader callback source file.

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.576.1 Detailed Description

Bootloader callback source file.

7.576.2 Function Documentation

7.576.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.576.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.576.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.576.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.576.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.576.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.576.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.576.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.576.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.576.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.576.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.576.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.577 hooks.c File Reference

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

- `blt_int8u NvmWriteHook (blt_addr addr, blt_int32u len, blt_int8u *data)`

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the data hasn't been written yet.

- `blt_int8u NvmEraseHook (blt_addr addr, blt_int32u len)`

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook (void)`

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook (blt_int8u resource, blt_int8u *seed)`

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.577.1 Detailed Description

Bootloader callback source file.

7.577.2 Function Documentation

7.577.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.577.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.577.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.577.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.577.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.577.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.577.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.577.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.577.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.577.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.577.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.577.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.577.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.577.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.577.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.578 hooks.c File Reference

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.578.1 Detailed Description

Bootloader callback source file.

7.578.2 Function Documentation

7.578.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.578.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.578.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.578.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.578.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.578.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.578.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.578.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.578.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.578.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.578.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.578.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.578.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.578.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.578.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.579 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
```

```
#include "stm32f1xx_ll_gpio.h"

Callback that gets called at the end of the NVM programming session.
- [blt_int8u](#) [XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.579.1 Detailed Description

Bootloader callback source file.

7.579.2 Function Documentation

7.579.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.579.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.579.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.579.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.579.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.579.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.579.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.579.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.579.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.579.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.579.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.579.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.579.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.579.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.579.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.580.1 Detailed Description

Bootloader callback source file.

7.580.2 Function Documentation

7.580.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.580.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.580.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.580.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.580.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.580.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.580.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.580.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.580.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.580.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.580.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.580.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.580.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.580.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.580.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.581 hooks.c File Reference

- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool NvmDoneHook](#) (void)
Callback that gets called at the end of the NVM programming session.
- [blt_bool FileIsFirmwareUpdateRequestedHook](#) (void)
Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.
- const [blt_char](#) * [FileGetFirmwareFilenameHook](#) (void)
Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.
- void [FileFirmwareUpdateStartedHook](#) (void)
Callback that gets called to inform the application that a firmware update from local storage just started.
- void [FileFirmwareUpdateCompletedHook](#) (void)
Callback that gets called to inform the application that a firmware update was successfully completed.

- void `FileFirmwareUpdateErrorHook` (`blt_int8u` error_code)
Callback that gets called in case an error occurred during a firmware update. Refer to <file.h> for a list of available error codes.
- void `FileFirmwareUpdateLogHook` (`blt_char` *info_string)
Callback that gets called each time new log information becomes available during a firmware update.
- `blt_int8u` `XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u` *seed)
Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.
- `blt_int8u` `XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u` *key, `blt_int8u` len)
Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const `blt_char` `firmwareFilename` [] = "/demoprogram_olimex_stm32p103.srec"
Firmware filename.
- ```

struct {
 FIL handle
 blt_bool canUse
} logfile

```

*Data structure for grouping log-file related information.*

## 7.581.1 Detailed Description

Bootloader callback source file.

## 7.581.2 Function Documentation

### 7.581.2.1 BackDoorEntryHook()

```

blt_bool BackDoorEntryHook (
 void)

```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.581.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.581.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.581.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.581.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.581.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

#### 7.581.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.581.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

##### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

##### Returns

none.

#### 7.581.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.581.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.581.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

**7.581.2.12 NvmDoneHook()**

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

**Returns**

BLT\_TRUE is successful, BLT\_FALSE otherwise.

**7.581.2.13 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

**7.581.2.14 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

**7.581.2.15 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

**7.581.2.16 NvmWriteHook()**

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

## Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

## 7.581.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

## Returns

Length of the seed in bytes.

## 7.581.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

**7.581.3 Variable Documentation****7.581.3.1 canUse**

`blt_bool` canUse

Flag to indicate if the log-file can be used.

**7.581.3.2 handle**

`FIL` handle

FatFS handle to the log-file.

**7.582 hooks.c File Reference**

*Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.*

## Variables

- static const `blt_char firmwareFilename []` = `"/demoprogram_olimex_stm32p103.srec"`  
*Firmware filename.*
- ```
struct {  
    FIL handle  
    blt_bool canUse  
} logfile
```

Data structure for grouping log-file related information.

7.582.1 Detailed Description

Bootloader callback source file.

7.582.2 Function Documentation

7.582.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.582.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.582.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.582.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.582.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.582.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.582.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.582.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.582.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.582.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.582.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.582.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.582.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.582.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.582.2.15 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.582.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.582.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.582.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.582.3 Variable Documentation

7.582.3.1 canUse

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.582.3.2 handle

FIL handle

FatFS handle to the log-file.

7.583 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"

## 7.583.1 Detailed Description

Bootloader callback source file.

## 7.583.2 Function Documentation

#### 7.583.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

##### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

#### 7.583.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

##### Returns

none.

#### 7.583.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

##### Returns

none.

#### 7.583.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.583.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.583.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

#### 7.583.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.583.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

**Returns**

none.

**7.583.2.9 FileFirmwareUpdateStartedHook()**

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.583.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.583.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

### 7.583.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

### 7.583.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

### 7.583.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

### 7.583.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.583.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

### 7.583.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

#### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.583.2.18 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

**7.583.3 Variable Documentation****7.583.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

**7.583.3.2 handle**

```
FIL handle
```

FatFS handle to the log-file.

## 7.584 hooks.c File Reference

Bootloader callback source file.

## Functions

- void [BackDoorInitHook](#) (void)  
*Initializes the backdoor entry option.*
- [blt\\_bool BackDoorEntryHook](#) (void)  
*Checks if a backdoor entry is requested.*
- [blt\\_bool CpuUserProgramStartHook](#) (void)  
*Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.*
- void [CopInitHook](#) (void)  
*Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.*
- void [CopServiceHook](#) (void)  
*Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.*
- void [NvmInitHook](#) (void)  
*Callback that gets called at the start of the internal NVM driver initialization routine.*
- void [NvmReinitHook](#) (void)  
*Callback that gets called at the start of a firmware update to reinitialize the NVM driver.*
- [blt\\_int8u NvmWriteHook](#) ([blt\\_addr](#) addr, [blt\\_int32u](#) len, [blt\\_int8u](#) \*data)  
*Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.*
- [blt\\_int8u NvmEraseHook](#) ([blt\\_addr](#) addr, [blt\\_int32u](#) len)  
*Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.*
- [blt\\_bool NvmDoneHook](#) (void)  
*Callback that gets called at the end of the NVM programming session.*
- [blt\\_bool FileIsFirmwareUpdateRequestedHook](#) (void)

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

- const `blt_char * FileGetFirmwareFilenameHook` (void)

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- void `FileFirmwareUpdateStartedHook` (void)

Callback that gets called to inform the application that a firmware update from local storage just started.

- void `FileFirmwareUpdateCompletedHook` (void)

Callback that gets called to inform the application that a firmware update was successfully completed.

- void `FileFirmwareUpdateErrorHook` (blt\_int8u error\_code)

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

- void `FileFirmwareUpdateLogHook` (blt\_char \*info\_string)

Callback that gets called each time new log information becomes available during a firmware update.

- blt\_int8u `XcpGetSeedHook` (blt\_int8u resource, blt\_int8u \*seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- blt\_int8u `XcpVerifyKeyHook` (blt\_int8u resource, blt\_int8u \*key, blt\_int8u len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## Variables

- static const `blt_char firmwareFilename` [] = `"/demoprogram_olimex_stm32p103.srec"`

Firmware filename.

- 

```
struct {
 FIL handle
 blt_bool canUse
} logfile
```

Data structure for grouping log-file related information.

## 7.584.1 Detailed Description

Bootloader callback source file.

## 7.584.2 Function Documentation

### 7.584.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

#### 7.584.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

##### Returns

none.

#### 7.584.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

##### Returns

none.

#### 7.584.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.584.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.584.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

#### 7.584.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.584.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

##### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

##### Returns

none.

#### 7.584.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.584.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.584.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

**7.584.2.12 NvmDoneHook()**

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

**Returns**

BLT\_TRUE is successful, BLT\_FALSE otherwise.

**7.584.2.13 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.584.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.584.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.584.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.584.2.17 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.584.2.18 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

### Returns

1 if the key was correct, 0 otherwise.

## 7.584.3 Variable Documentation

### 7.584.3.1 canUse

`blt_bool` canUse

Flag to indicate if the log-file can be used.

### 7.584.3.2 handle

FIL handle

FatFS handle to the log-file.

## 7.585.1 Detailed Description

Bootloader callback source file.

## 7.585.2 Function Documentation

### 7.585.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.585.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.585.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.585.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.585.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.585.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

#### Returns

none.

#### 7.585.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

##### Returns

none.

#### 7.585.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

##### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

##### Returns

none.

#### 7.585.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

##### Returns

none.

#### 7.585.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

##### Returns

valid firmware filename with full path or BLT\_NULL.

### 7.585.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

#### Returns

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

### 7.585.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

### 7.585.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.585.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

#### 7.585.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

#### 7.585.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

#### 7.585.2.17 UsbConnectHook()

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

##### Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

##### Returns

none.

#### 7.585.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

##### Returns

none.

#### 7.585.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

##### Returns

none.

#### 7.585.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

## Returns

Length of the seed in bytes.

## 7.585.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.585.3 Variable Documentation

## 7.585.3.1 canUse

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

## 7.585.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

## 7.586 hooks.c File Reference

Bootloader callback source file.

*Firmware filename.*
- ```

struct {
    FIL handle
    blt\_bool canUse
} logfile

```

Data structure for grouping log-file related information.

7.586.1 Detailed Description

Bootloader callback source file.

7.586.2 Function Documentation

7.586.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.586.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.586.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.586.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.586.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.586.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.586.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (  
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.586.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (  
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.586.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.586.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.586.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.586.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.586.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.586.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.586.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.586.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.586.2.17 UsbConnectHook()

```
void UsbConnectHook (  
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.586.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.586.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.586.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.586.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.586.3 Variable Documentation**7.586.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.586.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.587 hooks.c File Reference

### 7.587.1 Detailed Description

Bootloader callback source file.

### 7.587.2 Function Documentation

### 7.587.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.587.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.587.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.587.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

#### 7.587.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.587.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

#### 7.587.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.587.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

**Returns**

none.

**7.587.2.9 FileFirmwareUpdateStartedHook()**

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.587.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.587.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

#### 7.587.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.587.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.587.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

### 7.587.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.587.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

### 7.587.2.17 UsbConnectHook()

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

#### Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.587.2.18 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.587.2.19 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

**7.587.2.20 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.587.2.21 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

**7.587.3 Variable Documentation****7.587.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

**7.587.3.2 handle**

```
FIL handle
```

FatFS handle to the log-file.

## 7.588 hooks.c File Reference

- const [blt\\_char](#) \* [FileGetFirmwareFilenameHook](#) (void)  
*Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.*
- void [FileFirmwareUpdateStartedHook](#) (void)  
*Callback that gets called to inform the application that a firmware update from local storage just started.*
- void [FileFirmwareUpdateCompletedHook](#) (void)  
*Callback that gets called to inform the application that a firmware update was successfully completed.*
- void [FileFirmwareUpdateErrorHook](#) ([blt\\_int8u](#) error\_code)  
*Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.*
- void [FileFirmwareUpdateLogHook](#) ([blt\\_char](#) \*info\_string)  
*Callback that gets called each time new log information becomes available during a firmware update.*
- [blt\\_int8u XcpGetSeedHook](#) ([blt\\_int8u](#) resource, [blt\\_int8u](#) \*seed)  
*Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.*
- [blt\\_int8u XcpVerifyKeyHook](#) ([blt\\_int8u](#) resource, [blt\\_int8u](#) \*key, [blt\\_int8u](#) len)  
*Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.*

## Variables

- static const [blt\\_char](#) [firmwareFilename](#) [] = "/demoprogram\_olimexino\_stm32.srec"  
*Firmware filename.*
- ```

struct {
    FIL handle
    blt\_bool canUse
} logfile

```

Data structure for grouping log-file related information.

7.588.1 Detailed Description

Bootloader callback source file.

7.588.2 Function Documentation

7.588.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.588.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.588.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.588.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.588.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.588.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.588.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.588.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.588.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.588.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.588.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.588.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.588.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.588.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.588.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.588.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.588.2.17 UsbConnectHook()

```
void UsbConnectHook (  
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.588.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.588.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.588.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.588.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.588.3 Variable Documentation**7.588.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.588.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.589 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f2xx.h"
#include "stm32f2xx_ll_gpio.h"
#include "stm32f2xx_ll_usart.h"
```

Include dependency graph for ARMCM3_STM32F2_Olimex_STM32P207_CubeIDE/Boot/App/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool](#) [BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool](#) [NvmDoneHook](#) (void)
Callback that gets called at the end of the NVM programming session.
- [blt_bool](#) [FileIsFirmwareUpdateRequestedHook](#) (void)

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

- const `blt_char * FileGetFirmwareFilenameHook` (void)

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- void `FileFirmwareUpdateStartedHook` (void)

Callback that gets called to inform the application that a firmware update from local storage just started.

- void `FileFirmwareUpdateCompletedHook` (void)

Callback that gets called to inform the application that a firmware update was successfully completed.

- void `FileFirmwareUpdateErrorHook` (blt_int8u error_code)

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

- void `FileFirmwareUpdateLogHook` (blt_char *info_string)

Callback that gets called each time new log information becomes available during a firmware update.

- blt_int8u `XcpGetSeedHook` (blt_int8u resource, blt_int8u *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- blt_int8u `XcpVerifyKeyHook` (blt_int8u resource, blt_int8u *key, blt_int8u len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const `blt_char firmwareFilename` [] = `"/demoprogram_stm32f207.srec"`

Firmware filename.

-

```
struct {

} logfile
```

Data structure for grouping log-file related information.

7.589.1 Detailed Description

Bootloader callback source file.

7.589.2 Function Documentation

7.589.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.589.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.589.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.589.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.589.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.589.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.589.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.589.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.589.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.589.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.589.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.589.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.589.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (  
    blt_addr addr,  
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.589.2.14 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.589.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.589.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.589.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.589.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.589.3 Variable Documentation**7.589.3.1 canUse**

`blt_bool` canUse

Flag to indicate if the log-file can be used.

7.589.3.2 handle

`FIL` handle

FatFS handle to the log-file.

7.590 hooks.c File Reference

Bootloader callback source file.

Callback that gets called to inform the application that a firmware update was successfully completed.
- void [FileFirmwareUpdateErrorHook](#) ([blt_int8u](#) error_code)
Callback that gets called in case an error occurred during a firmware update. Refer to <file.h> for a list of available error codes.
- void [FileFirmwareUpdateLogHook](#) ([blt_char](#) *info_string)
Callback that gets called each time new log information becomes available during a firmware update.
- [blt_int8u XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)
Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.
- [blt_int8u XcpVerifyKeyHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *key, [blt_int8u](#) len)
Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const `blt_char firmwareFilename []` = `"/demoprogram_stm32f207.srec"`
Firmware filename.
- ```
struct {
 FIL handle
 blt_bool canUse
} logfile
```

*Data structure for grouping log-file related information.*

### 7.590.1 Detailed Description

Bootloader callback source file.

### 7.590.2 Function Documentation

#### 7.590.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

#### 7.590.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.590.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.590.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.590.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.590.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

#### Returns

none.

#### 7.590.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.590.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

##### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

##### Returns

none.

#### 7.590.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

##### Returns

none.

#### 7.590.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

##### Returns

valid firmware filename with full path or BLT\_NULL.

#### 7.590.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

##### Returns

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

#### 7.590.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.590.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.590.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

#### 7.590.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

#### 7.590.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

### 7.590.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

#### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

#### Returns

Length of the seed in bytes.

### 7.590.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

#### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

#### Returns

1 if the key was correct, 0 otherwise.

## 7.590.3 Variable Documentation

### 7.590.3.1 canUse

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

### 7.590.3.2 handle

FIL handle

FatFS handle to the log-file.

## 7.591 hooks.c File Reference

Bootloader callback source file.

7.591.1 Detailed Description

Bootloader callback source file.

7.591.2 Function Documentation

7.591.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.591.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.591.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.591.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.591.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.591.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.591.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.591.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.591.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.591.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.591.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.591.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.591.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.591.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.591.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.591.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.591.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.591.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.591.3 Variable Documentation**7.591.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.591.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.592 hooks.c File Reference

Bootloader callback source file.

7.592.1 Detailed Description

Bootloader callback source file.

7.592.2 Function Documentation

7.592.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.592.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.592.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.592.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.592.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.592.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.592.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.592.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.592.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.592.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.592.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.592.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.592.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (  
    blt_addr addr,  
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.592.2.14 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.592.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.592.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.592.2.17 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.592.2.18 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.592.3 Variable Documentation

7.592.3.1 canUse

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.592.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.593 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "device_registers.h"
```

Include dependency graph for ARMCM4_S32K14_S32K144EVB_GCC/Boot/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.593.1 Detailed Description

Bootloader callback source file.

7.593.2 Function Documentation

7.593.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.593.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.593.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.593.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.593.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.593.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.593.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR is the erase operation failed.

7.593.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.593.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.593.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.593.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.593.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.594.1 Detailed Description

Bootloader callback source file.

7.594.2 Function Documentation

7.594.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.594.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.594.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.594.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.594.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.594.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.594.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.594.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.594.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.594.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.594.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.594.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.595 hooks.c File Reference

7.595.1 Detailed Description

Bootloader callback source file.

7.595.2 Function Documentation

7.595.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.595.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.595.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.595.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.595.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.595.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.595.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.595.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.595.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.595.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.595.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.595.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.595.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.595.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.595.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.596 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f3xx.h"
```

```
#include "stm32f3xx_ll_gpio.h"
```

Include dependency graph for ARMCM4_STM32F3_Discovery_F303VC_GCC/Boot/hooks.c:

Functions

- [blt_bool CpuUserProgramStartHook](#) (void)

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [UsbConnectHook](#) (blt_bool connect)

Callback that gets called whenever the USB device should be connected to the USB bus.
- void [UsbEnterLowPowerModeHook](#) (void)

Callback that gets called whenever the USB host requests the device to enter a low power mode.
- void [UsbLeaveLowPowerModeHook](#) (void)

Callback that gets called whenever the USB host requests the device to exit low power mode.
- void [CopInitHook](#) (void)

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [BackDoorInitHook](#) (void)

Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)

Checks if a backdoor entry is requested.
- void [NvmInitHook](#) (void)

Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) (blt_addr addr, blt_int32u len, blt_int8u *data)

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) (blt_addr addr, blt_int32u len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool NvmDoneHook](#) (void)

Callback that gets called at the end of the NVM programming session.
- [blt_int8u XcpGetSeedHook](#) (blt_int8u resource, blt_int8u *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.596.1 Detailed Description

Bootloader callback source file.

7.596.2 Function Documentation

7.596.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.596.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.596.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.596.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.596.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.596.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.596.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.596.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.596.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.596.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.596.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.596.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.596.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.596.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.596.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.597.1 Detailed Description

Bootloader callback source file.

7.597.2 Function Documentation

7.597.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.597.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.597.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.597.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.597.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.597.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.597.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.597.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.597.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.597.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.597.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.597.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.597.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.597.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.597.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.598.1 Detailed Description

Bootloader callback source file.

7.598.2 Function Documentation

7.598.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.598.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.598.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.598.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.598.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.598.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.598.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.598.2.8 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.598.2.9 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.598.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.598.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.598.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.598.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.598.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.598.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [BackDoorInitHook](#) (void)

Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)

Checks if a backdoor entry is requested.
- void [NvmInitHook](#) (void)

Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool NvmDoneHook](#) (void)

Callback that gets called at the end of the NVM programming session.
- [blt_int8u XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.
- [blt_int8u XcpVerifyKeyHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *key, [blt_int8u](#) len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.599.1 Detailed Description

Bootloader callback source file.

7.599.2 Function Documentation

7.599.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.599.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.599.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.599.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.599.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.599.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.599.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.599.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.599.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.599.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.599.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.599.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.600 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f3xx.h"

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *`seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.600.1 Detailed Description

Bootloader callback source file.

7.600.2 Function Documentation

7.600.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.600.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.600.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.600.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.600.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.600.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.600.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.600.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.600.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.600.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.600.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.600.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u` *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u` *key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.601.1 Detailed Description

Bootloader callback source file.

7.601.2 Function Documentation

7.601.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.601.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.601.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.601.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.601.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.601.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.601.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.601.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.601.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.601.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.601.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.601.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.602.1 Detailed Description

Bootloader callback source file.

7.602.2 Function Documentation

7.602.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.602.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.602.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.602.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.602.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.602.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.602.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.602.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.602.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.602.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.602.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.602.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.603 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f4xx.h"
```

Include dependency graph for ARMCM4_STM32F4_Nucleo_F429ZI_CubeIDE/Boot/App/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [UsbConnectHook](#) ([blt_bool](#) connect)
Callback that gets called whenever the USB device should be connected to the USB bus.
- void [UsbEnterLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to enter a low power mode.
- void [UsbLeaveLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to exit low power mode.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

- `blt_int8u NvmWriteHook (blt_addr addr, blt_int32u len, blt_int8u *data)`

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the data hasn't been written yet.

- `blt_int8u NvmEraseHook (blt_addr addr, blt_int32u len)`

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook (void)`

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook (blt_int8u resource, blt_int8u *seed)`

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.603.1 Detailed Description

Bootloader callback source file.

7.603.2 Function Documentation

7.603.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.603.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.603.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.603.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.603.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.603.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.603.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.603.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.603.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.603.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.603.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.603.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.603.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.603.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.603.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.604.1 Detailed Description

Bootloader callback source file.

7.604.2 Function Documentation

7.604.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.604.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.604.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.604.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.604.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.604.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.604.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.604.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.604.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.604.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.604.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.604.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.604.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.604.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.604.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.605.1 Detailed Description

Bootloader callback source file.

7.605.2 Function Documentation

7.605.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.605.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.605.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.605.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.605.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.605.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.605.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.605.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.605.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.605.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.605.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.605.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.605.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.605.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed if requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer wher the seed will be stored.

Returns

Length of the seed in bytes.

7.605.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.606 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
```

```
#include "stm32f4xx.h"
```

Include dependency graph for ARMCM4_STM32F4_Nucleo_F429ZI_Keil/Boot/hooks.c:

Functions

- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [UsbConnectHook](#) ([blt_bool](#) connect)
Callback that gets called whenever the USB device should be connected to the USB bus.
- void [UsbEnterLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to enter a low power mode.
- void [UsbLeaveLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to exit low power mode.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool NvmDoneHook](#) (void)
Callback that gets called at the end of the NVM programming session.

- [blt_int8u XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- [blt_int8u XcpVerifyKeyHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *key, [blt_int8u](#) len)

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.606.1 Detailed Description

Bootloader callback source file.

7.606.2 Function Documentation

7.606.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.606.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.606.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.606.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.606.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.606.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.606.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.606.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.606.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.606.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.606.2.11 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.606.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.606.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.606.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.606.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Callback that gets called whenever the USB host requests the device to enter a low power mode.
- void [UsbLeaveLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to exit low power mode.
- [blt_bool](#) [FileIsFirmwareUpdateRequestedHook](#) (void)
Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.
- const [blt_char](#) * [FileGetFirmwareFilenameHook](#) (void)

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- void [FileFirmwareUpdateStartedHook](#) (void)

Callback that gets called to inform the application that a firmware update from local storage just started.

- void [FileFirmwareUpdateCompletedHook](#) (void)

Callback that gets called to inform the application that a firmware update was successfully completed.

- void [FileFirmwareUpdateErrorHook](#) (blt_int8u error_code)

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

- void [FileFirmwareUpdateLogHook](#) (blt_char *info_string)

Callback that gets called each time new log information becomes available during a firmware update.

- [blt_int8u XcpGetSeedHook](#) (blt_int8u resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- [blt_int8u XcpVerifyKeyHook](#) (blt_int8u resource, [blt_int8u](#) *key, [blt_int8u](#) len)

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const [blt_char firmwareFilename](#) [] = "/demoprogram_olimex_stm32p405.srec"

Firmware filename.

-

```
struct {
    FIL handle
    blt_bool canUse
} logfile
```

Data structure for grouping log-file related information.

7.607.1 Detailed Description

Bootloader callback source file.

7.607.2 Function Documentation

7.607.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.607.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.607.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.607.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.607.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.607.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.607.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (  
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.607.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (  
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.607.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.607.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.607.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.607.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.607.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.607.2.14 NvmInitHook()

```
void NvmInitHook (  
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.607.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.607.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.607.2.17 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.607.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.607.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.607.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.607.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.607.3 Variable Documentation

7.607.3.1 canUse

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.607.3.2 handle

FIL handle

FatFS handle to the log-file.

7.608 hooks.c File Reference

Bootloader callback source file.

```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- void `UsbConnectHook` (`blt_bool` connect)

Callback that gets called whenever the USB device should be connected to the USB bus.

- void `UsbEnterLowPowerModeHook` (void)

Callback that gets called whenever the USB host requests the device to enter a low power mode.

- void `UsbLeaveLowPowerModeHook` (void)

Callback that gets called whenever the USB host requests the device to exit low power mode.

- `blt_bool` `FileIsFirmwareUpdateRequestedHook` (void)

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

- const `blt_char` * `FileGetFirmwareFilenameHook` (void)

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- void `FileFirmwareUpdateStartedHook` (void)

Callback that gets called to inform the application that a firmware update from local storage just started.

- void `FileFirmwareUpdateCompletedHook` (void)

Callback that gets called to inform the application that a firmware update was successfully completed.

- void `FileFirmwareUpdateErrorHook` (`blt_int8u` error_code)

Callback that gets called in case an error occurred during a firmware update. Refer to [<file.h>](#) for a list of available error codes.

- void `FileFirmwareUpdateLogHook` (`blt_char` *info_string)

Callback that gets called each time new log information becomes available during a firmware update.

- `blt_int8u` `XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u` *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u` `XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u` *key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- static const `blt_char` `firmwareFilename` [] = `"/demoprogram_olimex_stm32p405.srec"`

Firmware filename.

7.608.1 Detailed Description

Bootloader callback source file.

7.608.2 Function Documentation

7.608.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.608.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.608.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.608.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.608.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.608.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.608.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.608.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.608.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.608.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.608.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.608.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.608.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.608.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.608.2.15 NvmReinitHook()

```
void NvmReinitHook (  
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.608.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (  
    blt_addr addr,  
    blt_int32u len,  
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.608.2.17 UsbConnectHook()

```
void UsbConnectHook (  
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.608.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.608.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.608.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.608.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.608.3 Variable Documentation**7.608.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.608.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.609 hooks.c File Reference

## 7.609.1 Detailed Description

Bootloader callback source file.

## 7.609.2 Function Documentation

### 7.609.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.609.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.609.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.609.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

#### 7.609.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.609.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

#### 7.609.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

##### Returns

none.

#### 7.609.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

**Returns**

none.

**7.609.2.9 FileFirmwareUpdateStartedHook()**

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.609.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.609.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

#### 7.609.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.609.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.609.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

### 7.609.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.609.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

### 7.609.2.17 UsbConnectHook()

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

#### Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.609.2.18 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.609.2.19 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

**7.609.2.20 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.609.2.21 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

**7.609.3 Variable Documentation****7.609.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

**7.609.3.2 handle**

```
FIL handle
```

FatFS handle to the log-file.

7.610.1 Detailed Description

Bootloader callback source file.

7.610.2 Function Documentation

7.610.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.610.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.610.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.610.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.610.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.610.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.610.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.610.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.610.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.610.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.610.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.610.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.610.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.610.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.610.2.15 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.610.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.610.2.17 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	BLT_TRUE to connect and BLT_FALSE to disconnect.
----------------	--

Returns

none.

7.610.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.610.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.610.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.610.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.610.3 Variable Documentation**7.610.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.610.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.611 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l4xx.h"
#include "stm32l4xx_ll_gpio.h"
```

Include dependency graph for ARMC4_STM32L4_Nucleo_L476RG_CubeIDE/Boot/App/hooks.c:

Functions

- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)
Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.
- [blt_bool NvmDoneHook](#) (void)
Callback that gets called at the end of the NVM programming session.

- [blt_int8u XcpGetSeedHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

- [blt_int8u XcpVerifyKeyHook](#) ([blt_int8u](#) resource, [blt_int8u](#) *key, [blt_int8u](#) len)

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.611.1 Detailed Description

Bootloader callback source file.

7.611.2 Function Documentation

7.611.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.611.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.611.2.3 CopInitHook()

```
void CopInitHook (
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.611.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.611.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.611.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.611.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.611.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.611.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.611.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.611.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.611.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.612 hooks.c File Reference

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.612.1 Detailed Description

Bootloader callback source file.

7.612.2 Function Documentation

7.612.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.612.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.612.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.612.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.612.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.612.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.612.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.612.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.612.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.612.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.612.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.612.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.613 hooks.c File Reference

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.613.1 Detailed Description

Bootloader callback source file.

7.613.2 Function Documentation

7.613.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.613.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.613.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.613.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.613.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.613.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.613.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.613.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.613.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.613.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.613.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.613.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.614 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l4xx.h"
#include "stm32l4xx_ll_gpio.h"
```

Include dependency graph for ARMCM4_STM32L4_Nucleo_L476RG_Keil/Boot/hooks.c:

Functions

- [blt_bool CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [CopInitHook](#) (void)
Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.
- void [CopServiceHook](#) (void)
Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.
- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

7.614.1 Detailed Description

Bootloader callback source file.

7.614.2 Function Documentation

7.614.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
    void )
```

Checks if a backdoor entry is requested.

Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

7.614.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.614.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.614.2.4 CopServiceHook()

```
void CopServiceHook (  
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.614.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (  
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.614.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (  
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.614.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the erase operation failed.

7.614.2.8 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.614.2.9 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.614.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR if the write operation failed.

7.614.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
    blt_int8u resource,
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.614.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

Functions

- void [UsbConnectHook](#) ([blt_bool](#) connect)
Callback that gets called whenever the USB device should be connected to the USB bus.
- void [UsbEnterLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to enter a low power mode.
- void [UsbLeaveLowPowerModeHook](#) (void)
Callback that gets called whenever the USB host requests the device to exit low power mode.
- void [BackDoorInitHook](#) (void)
Initializes the backdoor entry option.
- [blt_bool](#) [BackDoorEntryHook](#) (void)
Checks if a backdoor entry is requested.
- [blt_bool](#) [CpuUserProgramStartHook](#) (void)
Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.
- void [NvmInitHook](#) (void)
Callback that gets called at the start of the internal NVM driver initialization routine.
- void [NvmReinitHook](#) (void)
Callback that gets called at the start of a firmware update to reinitialize the NVM driver.
- [blt_int8u](#) [NvmWriteHook](#) ([blt_addr](#) addr, [blt_int32u](#) len, [blt_int8u](#) *data)
Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the data hasn't been written yet.
- [blt_int8u](#) [NvmEraseHook](#) ([blt_addr](#) addr, [blt_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook (void)`

Callback that gets called at the end of the NVM programming session.

- `void CopInitHook (void)`

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

- `void CopServiceHook (void)`

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

- `blt_bool FileIsFirmwareUpdateRequestedHook (void)`

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

- `const blt_char * FileGetFirmwareFilenameHook (void)`

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

- `void FileFirmwareUpdateStartedHook (void)`

Callback that gets called to inform the application that a firmware update from local storage just started.

- `void FileFirmwareUpdateCompletedHook (void)`

Callback that gets called to inform the application that a firmware update was successfully completed.

- `void FileFirmwareUpdateErrorHook (blt_int8u error_code)`

Callback that gets called in case an error occurred during a firmware update. Refer to `<file.h>` for a list of available error codes.

- `void FileFirmwareUpdateLogHook (blt_char *info_string)`

Callback that gets called each time new log information becomes available during a firmware update.

- `blt_int8u XcpGetSeedHook (blt_int8u resource, blt_int8u *seed)`

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Variables

- `static const blt_char firmwareFilename [] = "/demoprogram_dk_tm4c123g.srec"`

Firmware filename.

-

```
struct {
    FIL handle
    blt_bool canUse
} logfile
```

Data structure for grouping log-file related information.

7.615.1 Detailed Description

Bootloader callback source file.

7.615.2 Function Documentation

7.615.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (  
    void )
```

Checks if a backdoor entry is requested.

Returns

BLT_TRUE if the backdoor entry is requested, BLT_FALSE otherwise.

7.615.2.2 BackDoorInitHook()

```
void BackDoorInitHook (  
    void )
```

Initializes the backdoor entry option.

Returns

none.

7.615.2.3 CopInitHook()

```
void CopInitHook (  
    void )
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

Returns

none.

7.615.2.4 CopServiceHook()

```
void CopServiceHook (
    void )
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

Returns

none.

7.615.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
    void )
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

Returns

BLT_TRUE if it is okay to start the user program, BLT_FALSE to keep keep the bootloader active.

7.615.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
    void )
```

Callback that gets called to inform the application that a firmware update was successfully completed.

Returns

none.

7.615.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
    blt_int8u error_code )
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

Returns

none.

7.615.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
    blt_char * info_string )
```

Callback that gets called each time new log information becomes available during a firmware update.

Parameters

<i>info_string</i>	Pointer to a character array with the log entry info.
--------------------	---

Returns

none.

7.615.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (  
    void )
```

Callback that gets called to inform the application that a firmware update from local storage just started.

Returns

none.

7.615.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (  
    void )
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

Returns

valid firmware filename with full path or BLT_NULL.

7.615.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (  
    void )
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

Returns

BLT_TRUE if a firmware update is requested, BLT_FALSE otherwise.

7.615.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
    void )
```

Callback that gets called at the end of the NVM programming session.

Returns

BLT_TRUE is successful, BLT_FALSE otherwise.

7.615.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
    blt_addr addr,
    blt_int32u len )
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT_NVM_NOT_IN_RANGE must be returned to indicate that the memory hasn't been erased yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.

Returns

BLT_NVM_OKAY if successful, BLT_NVM_NOT_IN_RANGE if the address is not within the supported memory range, or BLT_NVM_ERROR is the erase operation failed.

7.615.2.14 NvmInitHook()

```
void NvmInitHook (
    void )
```

Callback that gets called at the start of the internal NVM driver initialization routine.

Returns

none.

7.615.2.15 NvmReinitHook()

```
void NvmReinitHook (
    void )
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

Returns

none.

7.615.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
    blt_addr addr,
    blt_int32u len,
    blt_int8u * data )
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the data hasn't been written yet.

Parameters

<i>addr</i>	Start address.
<i>len</i>	Length in bytes.
<i>data</i>	Pointer to the data buffer.

Returns

`BLT_NVM_OKAY` if successful, `BLT_NVM_NOT_IN_RANGE` if the address is not within the supported memory range, or `BLT_NVM_ERROR` if the write operation failed.

7.615.2.17 UsbConnectHook()

```
void UsbConnectHook (
    blt_bool connect )
```

Callback that gets called whenever the USB device should be connected to the USB bus.

Parameters

<i>connect</i>	<code>BLT_TRUE</code> to connect and <code>BLT_FALSE</code> to disconnect.
----------------	--

Returns

none.

7.615.2.18 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

Returns

none.

7.615.2.19 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (  
    void )
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

Returns

none.

7.615.2.20 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (  
    blt_int8u resource,  
    blt_int8u * seed )
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET_SEED command.

Parameters

<i>resource</i>	Resource that the seed is requested for (XCP_RES_XXX).
<i>seed</i>	Pointer to byte buffer where the seed will be stored.

Returns

Length of the seed in bytes.

7.615.2.21 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
    blt_int8u resource,
    blt_int8u * key,
    blt_int8u len )
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

Parameters

<i>resource</i>	resource to unlock (XCP_RES_XXX).
<i>key</i>	pointer to the byte buffer holding the key.
<i>len</i>	length of the key in bytes.

Returns

1 if the key was correct, 0 otherwise.

7.615.3 Variable Documentation**7.615.3.1 canUse**

```
blt_bool canUse
```

Flag to indicate if the log-file can be used.

7.615.3.2 handle

```
FIL handle
```

FatFS handle to the log-file.

7.616 hooks.c File Reference

Bootloader callback source file.

## 7.616.1 Detailed Description

Bootloader callback source file.

## 7.616.2 Function Documentation

### 7.616.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

#### 7.616.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

##### Returns

none.

#### 7.616.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

##### Returns

none.

#### 7.616.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.616.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.616.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

#### Returns

none.

### 7.616.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

#### Returns

none.

### 7.616.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

#### Returns

none.

### 7.616.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

**Returns**

none.

**7.616.2.10 FileGetFirmwareFilenameHook()**

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

**Returns**

valid firmware filename with full path or BLT\_NULL.

**7.616.2.11 FileIsFirmwareUpdateRequestedHook()**

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

**Returns**

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

**7.616.2.12 NvmDoneHook()**

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

**Returns**

BLT\_TRUE is successful, BLT\_FALSE otherwise.

**7.616.2.13 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.616.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.616.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.616.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.616.2.17 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.616.2.18 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

### Returns

1 if the key was correct, 0 otherwise.

## 7.616.3 Variable Documentation

### 7.616.3.1 canUse

`blt_bool` canUse

Flag to indicate if the log-file can be used.

### 7.616.3.2 handle

`FIL` handle

FatFS handle to the log-file.

## 7.617 hooks.c File Reference

### 7.617.1 Detailed Description

Bootloader callback source file.

### 7.617.2 Function Documentation

#### 7.617.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

#### 7.617.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

#### 7.617.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

##### Returns

none.

#### 7.617.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.617.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.617.2.6 FileFirmwareUpdateCompletedHook()

```
void FileFirmwareUpdateCompletedHook (
 void)
```

Callback that gets called to inform the application that a firmware update was successfully completed.

##### Returns

none.

Referenced by FileTask().

### 7.617.2.7 FileFirmwareUpdateErrorHook()

```
void FileFirmwareUpdateErrorHook (
 blt_int8u error_code)
```

Callback that gets called in case an error occurred during a firmware update. Refer to <[file.h](#)> for a list of available error codes.

#### Returns

none.

Referenced by FileTask().

### 7.617.2.8 FileFirmwareUpdateLogHook()

```
void FileFirmwareUpdateLogHook (
 blt_char * info_string)
```

Callback that gets called each time new log information becomes available during a firmware update.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <i>info_string</i> | Pointer to a character array with the log entry info. |
|--------------------|-------------------------------------------------------|

#### Returns

none.

Referenced by FileTask().

### 7.617.2.9 FileFirmwareUpdateStartedHook()

```
void FileFirmwareUpdateStartedHook (
 void)
```

Callback that gets called to inform the application that a firmware update from local storage just started.

#### Returns

none.

Referenced by FileTask().

#### 7.617.2.10 FileGetFirmwareFilenameHook()

```
const blt_char* FileGetFirmwareFilenameHook (
 void)
```

Callback to obtain the filename of the firmware file that should be used during the firmware update from the local file storage. This hook function is called at the beginning of the firmware update from local storage sequence.

##### Returns

valid firmware filename with full path or BLT\_NULL.

Referenced by FileTask().

#### 7.617.2.11 FileIsFirmwareUpdateRequestedHook()

```
blt_bool FileIsFirmwareUpdateRequestedHook (
 void)
```

Callback that gets called to check whether a firmware update from local file storage should be started. This could for example be when a switch is pressed, when a certain file is found on the local file storage, etc.

##### Returns

BLT\_TRUE if a firmware update is requested, BLT\_FALSE otherwise.

Referenced by FileHandleFirmwareUpdateRequest().

#### 7.617.2.12 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.617.2.13 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.617.2.14 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.617.2.15 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.617.2.16 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.617.2.17 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.617.2.18 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

**7.617.3 Variable Documentation****7.617.3.1 canUse**

`blt_bool` canUse

Flag to indicate if the log-file can be used.

**7.617.3.2 handle**

FIL handle

FatFS handle to the log-file.

**7.618 hooks.c File Reference**

### 7.618.1 Detailed Description

Bootloader callback source file.

### 7.618.2 Function Documentation

### 7.618.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.618.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.618.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.618.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

#### 7.618.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.618.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.618.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

### 7.618.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

### 7.618.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.618.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

#### 7.618.2.11 UsbConnectHook()

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

##### Parameters

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

##### Returns

none.

#### 7.618.2.12 UsbEnterLowPowerModeHook()

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

##### Returns

none.

#### 7.618.2.13 UsbLeaveLowPowerModeHook()

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

##### Returns

none.

#### 7.618.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

## Returns

Length of the seed in bytes.

## 7.618.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

*Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.*
- [blt\\_int8u NvmEraseHook](#) (blt\_addr addr, blt\_int32u len)  
*Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.*
- [blt\\_bool NvmDoneHook](#) (void)  
*Callback that gets called at the end of the NVM programming session.*
- [blt\\_int8u XcpGetSeedHook](#) (blt\_int8u resource, blt\_int8u \*seed)

*Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.*

- `blt_int8u XcpVerifyKeyHook (blt_int8u resource, blt_int8u *key, blt_int8u len)`

*Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.*

## 7.619.1 Detailed Description

Bootloader callback source file.

## 7.619.2 Function Documentation

### 7.619.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.619.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.619.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.619.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.619.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.619.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.619.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.619.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.619.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.619.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.619.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.619.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.619.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.619.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

##### Returns

Length of the seed in bytes.

#### 7.619.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.620.1 Detailed Description

Bootloader callback source file.

## 7.620.2 Function Documentation

### 7.620.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.620.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.620.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.620.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.620.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.620.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.620.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

**7.620.2.8 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

**7.620.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

**7.620.2.10 NvmWriteHook()**

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.620.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.620.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.620.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.620.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

##### Returns

Length of the seed in bytes.

#### 7.620.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.621.1 Detailed Description

Bootloader callback source file.

## 7.621.2 Function Documentation

### 7.621.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.621.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.621.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.621.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.621.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.621.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.621.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

**7.621.2.8 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

**7.621.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

**7.621.2.10 NvmWriteHook()**

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.621.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.621.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.621.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.621.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed if requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer wher the seed will be stored.   |

##### Returns

Length of the seed in bytes.

#### 7.621.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.622 hooks.c File Reference

## 7.622.1 Detailed Description

Bootloader callback source file.

## 7.622.2 Function Documentation

### 7.622.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.622.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.622.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.622.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.622.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.622.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.622.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.622.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.622.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.622.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.622.2.11 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.622.2.12 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.623 hooks.c File Reference

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *`seed)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *`key, `blt_int8u` len)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

### 7.623.1 Detailed Description

Bootloader callback source file.

### 7.623.2 Function Documentation

#### 7.623.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

#### 7.623.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.623.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.623.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.623.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.623.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.623.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.623.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

#### 7.623.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

#### 7.623.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

## Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

## 7.623.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

## Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

## Returns

Length of the seed in bytes.

## 7.623.2.12 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.624 hooks.c File Reference

Bootloader callback source file.

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

## 7.624.1 Detailed Description

Bootloader callback source file.

## 7.624.2 Function Documentation

### 7.624.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

### 7.624.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

#### 7.624.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

##### Returns

none.

#### 7.624.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.624.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.624.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

### 7.624.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

### 7.624.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

### 7.624.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.624.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.624.2.11 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.624.2.12 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.625 hooks.c File Reference

Bootloader callback source file.

*Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.*
- void [CopServiceHook](#) (void)  
*Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.*
- void [BackDoorInitHook](#) (void)  
*Initializes the backdoor entry option.*
- [blt\\_bool BackDoorEntryHook](#) (void)  
*Checks if a backdoor entry is requested.*
- void [NvmInitHook](#) (void)  
*Callback that gets called at the start of the internal NVM driver initialization routine.*
- void [NvmReinitHook](#) (void)  
*Callback that gets called at the start of a firmware update to reinitialize the NVM driver.*
- [blt\\_int8u NvmWriteHook](#) ([blt\\_addr](#) addr, [blt\\_int32u](#) len, [blt\\_int8u](#) \*data)  
*Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.*
- [blt\\_int8u NvmEraseHook](#) ([blt\\_addr](#) addr, [blt\\_int32u](#) len)

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then `BLT_NVM_NOT_IN_RANGE` must be returned to indicate that the memory hasn't been erased yet.

- `blt_bool NvmDoneHook` (void)

Callback that gets called at the end of the NVM programming session.

- `blt_int8u XcpGetSeedHook` (`blt_int8u` resource, `blt_int8u *seed`)

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the `GET_SEED` command.

- `blt_int8u XcpVerifyKeyHook` (`blt_int8u` resource, `blt_int8u *key`, `blt_int8u len`)

Called by the `UNLOCK` command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

### 7.625.1 Detailed Description

Bootloader callback source file.

### 7.625.2 Function Documentation

#### 7.625.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

`BLT_TRUE` if the backdoor entry is requested, `BLT_FALSE` otherwise.

#### 7.625.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.625.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.625.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.625.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.625.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.625.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

#### 7.625.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

#### 7.625.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

#### 7.625.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.625.2.11 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.625.2.12 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.626.1 Detailed Description

Bootloader callback source file.

## 7.626.2 Function Documentation

### 7.626.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.626.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.626.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

### 7.626.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

### 7.626.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

### 7.626.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

### 7.626.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

### 7.626.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

### 7.626.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

### 7.626.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.626.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.626.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.626.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.626.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

##### Returns

Length of the seed in bytes.

#### 7.626.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.627.1 Detailed Description

Bootloader callback source file.

## 7.627.2 Function Documentation

### 7.627.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.627.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.627.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.627.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.627.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.627.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.627.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

**7.627.2.8 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

**7.627.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

**7.627.2.10 NvmWriteHook()**

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.627.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.627.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.627.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.627.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

##### Returns

Length of the seed in bytes.

#### 7.627.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.628.1 Detailed Description

Bootloader callback source file.

## 7.628.2 Function Documentation

### 7.628.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.628.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.628.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.628.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.628.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.628.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.628.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

**7.628.2.8 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

**7.628.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

**7.628.2.10 NvmWriteHook()**

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.628.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.628.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.628.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.628.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

##### Returns

Length of the seed in bytes.

#### 7.628.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.629.1 Detailed Description

Bootloader callback source file.

## 7.629.2 Function Documentation

### 7.629.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.629.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.629.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.629.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.629.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.629.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.629.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.629.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.629.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.629.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.629.2.11 UsbConnectHook()**

```
void UsbConnectHook (
 blt_bool connect)
```

Callback that gets called whenever the USB device should be connected to the USB bus.

**Parameters**

|                |                                                  |
|----------------|--------------------------------------------------|
| <i>connect</i> | BLT_TRUE to connect and BLT_FALSE to disconnect. |
|----------------|--------------------------------------------------|

**Returns**

none.

**7.629.2.12 UsbEnterLowPowerModeHook()**

```
void UsbEnterLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to enter a low power mode.

**Returns**

none.

**7.629.2.13 UsbLeaveLowPowerModeHook()**

```
void UsbLeaveLowPowerModeHook (
 void)
```

Callback that gets called whenever the USB host requests the device to exit low power mode.

**Returns**

none.

#### 7.629.2.14 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

##### Parameters

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed if requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer wher the seed will be stored.   |

##### Returns

Length of the seed in bytes.

#### 7.629.2.15 XcpVerifyKeyHook()

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

##### Parameters

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

##### Returns

1 if the key was correct, 0 otherwise.

## 7.630.1 Detailed Description

Bootloader callback source file.

## 7.630.2 Function Documentation

### 7.630.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

### 7.630.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

### 7.630.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

#### 7.630.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

##### Returns

none.

#### 7.630.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

##### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

#### 7.630.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

#### 7.630.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

## Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

## 7.630.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

## Returns

none.

## 7.630.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

## Returns

none.

## 7.630.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

**7.630.2.11 XcpGetSeedHook()**

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

**7.630.2.12 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

## Returns

1 if the key was correct, 0 otherwise.

## 7.631 hooks.c File Reference

Bootloader callback source file.

```
#include "boot.h"
```

Include dependency graph for HCS12\_Evbplus\_Dragon12p\_CodeWarrior/Boot/hooks.c:

### Functions

### 7.631.1 Detailed Description

Bootloader callback source file.

### 7.631.2 Function Documentation

#### 7.631.2.1 BackDoorEntryHook()

```
blt_bool BackDoorEntryHook (
 void)
```

Checks if a backdoor entry is requested.

#### Returns

BLT\_TRUE if the backdoor entry is requested, BLT\_FALSE otherwise.

Referenced by BackDoorInit().

#### 7.631.2.2 BackDoorInitHook()

```
void BackDoorInitHook (
 void)
```

Initializes the backdoor entry option.

#### Returns

none.

Referenced by BackDoorInit().

### 7.631.2.3 CopInitHook()

```
void CopInitHook (
 void)
```

Callback that gets called at the end of the internal COP driver initialization routine. It can be used to configure and enable the watchdog.

#### Returns

none.

Referenced by CopInit().

### 7.631.2.4 CopServiceHook()

```
void CopServiceHook (
 void)
```

Callback that gets called at the end of the internal COP driver service routine. This gets called upon initialization and during potential long lasting loops and routine. It can be used to service the watchdog to prevent a watchdog reset.

#### Returns

none.

Referenced by CopService().

### 7.631.2.5 CpuUserProgramStartHook()

```
blt_bool CpuUserProgramStartHook (
 void)
```

Callback that gets called when the bootloader is about to exit and hand over control to the user program. This is the last moment that some final checking can be performed and if necessary prevent the bootloader from activating the user program.

#### Returns

BLT\_TRUE if it is okay to start the user program, BLT\_FALSE to keep keep the bootloader active.

Referenced by CpuStartUserProgram().

#### 7.631.2.6 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

#### 7.631.2.7 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

#### 7.631.2.8 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

### 7.631.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

Referenced by NvmReinit().

### 7.631.2.10 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.631.2.11 XcpGetSeedHook()

```
blt_int8u XcpGetSeedHook (
 blt_int8u resource,
 blt_int8u * seed)
```

Provides a seed to the XCP master that will be used for the key generation when the master attempts to unlock the specified resource. Called by the GET\_SEED command.

**Parameters**

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <i>resource</i> | Resource that the seed is requested for (XCP_RES_XXX). |
| <i>seed</i>     | Pointer to byte buffer where the seed will be stored.  |

**Returns**

Length of the seed in bytes.

Referenced by XcpGetSeed().

**7.631.2.12 XcpVerifyKeyHook()**

```
blt_int8u XcpVerifyKeyHook (
 blt_int8u resource,
 blt_int8u * key,
 blt_int8u len)
```

Called by the UNLOCK command and checks if the key to unlock the specified resource was correct. If so, then the resource protection will be removed.

**Parameters**

|                 |                                             |
|-----------------|---------------------------------------------|
| <i>resource</i> | resource to unlock (XCP_RES_XXX).           |
| <i>key</i>      | pointer to the byte buffer holding the key. |
| <i>len</i>      | length of the key in bytes.                 |

**Returns**

1 if the key was correct, 0 otherwise.

Referenced by XcpVerifyKey().

**7.632 irq.c File Reference**

IRQ driver source file.

```
#include "header.h"
```

Include dependency graph for irq.c:

## Functions

- void [IrqInterruptEnable](#) (void)  
*Enables the generation IRQ interrupts. Typically called once during software startup after completion of the initialization.*
- void [IrqInterruptDisable](#) (void)  
*Disables the generation IRQ interrupts and stores information on whether or not the interrupts were already disabled before explicitly disabling them with this function. Normally used as a pair together with [IrqInterruptRestore](#) during a critical section.*
- void [IrqInterruptRestore](#) (void)  
*Restore the generation IRQ interrupts to the setting it had prior to calling [IrqInterruptDisable](#). Normally used as a pair together with [IrqInterruptDisable](#) during a critical section.*

## Variables

- static volatile unsigned long [irqNesting](#) =0  
*IRQ nesting counter .*
- static volatile unsigned char [irqCCRregSave](#)  
*Copy of CCR register.*

### 7.632.1 Detailed Description

IRQ driver source file.

### 7.632.2 Function Documentation

#### 7.632.2.1 IrqInterruptDisable()

```
void IrqInterruptDisable (
 void)
```

Disables the generation IRQ interrupts and stores information on whether or not the interrupts were already disabled before explicitly disabling them with this function. Normally used as a pair together with IrqInterruptRestore during a critical section.

##### Returns

none.

#### 7.632.2.2 IrqInterruptEnable()

```
void IrqInterruptEnable (
 void)
```

Enables the generation IRQ interrupts. Typically called once during software startup after completion of the initialization.

##### Returns

none.

#### 7.632.2.3 IrqInterruptRestore()

```
void IrqInterruptRestore (
 void)
```

Restore the generation IRQ interrupts to the setting it had prior to calling IrqInterruptDisable. Normally used as a pair together with IrqInterruptDisable during a critical section.

##### Returns

none.

### 7.633 irq.h File Reference

IRQ driver header file.

## Functions

- void [IrqInterruptEnable](#) (void)  
*Enables the generation IRQ interrupts. Typically called once during software startup after completion of the initialization.*
- void [IrqInterruptDisable](#) (void)  
*Disables the generation IRQ interrupts and stores information on whether or not the interrupts were already disabled before explicitly disabling them with this function. Normally used as a pair together with [IrqInterruptRestore](#) during a critical section.*
- void [IrqInterruptRestore](#) (void)  
*Restore the generation IRQ interrupts to the setting it had prior to calling [IrqInterruptDisable](#). Normally used as a pair together with [IrqInterruptDisable](#) during a critical section.*

### 7.633.1 Detailed Description

IRQ driver header file.

### 7.633.2 Function Documentation

#### 7.633.2.1 IrqInterruptDisable()

```
void IrqInterruptDisable (
 void)
```

Disables the generation IRQ interrupts and stores information on whether or not the interrupts were already disabled before explicitly disabling them with this function. Normally used as a pair together with [IrqInterruptRestore](#) during a critical section.

#### Returns

none.

#### 7.633.2.2 IrqInterruptEnable()

```
void IrqInterruptEnable (
 void)
```

Enables the generation IRQ interrupts. Typically called once during software startup after completion of the initialization.

#### Returns

none.

### 7.633.2.3 IrqInterruptRestore()

```
void IrqInterruptRestore (
 void)
```

Restore the generation IRQ interrupts to the setting it had prior to calling IrqInterruptDisable. Normally used as a pair together with IrqInterruptDisable during a critical section.

#### Returns

none.

## 7.634 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
```

Include dependency graph for \_template/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.634.1 Detailed Description

LED driver source file.

### 7.634.2 Function Documentation

#### 7.634.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

##### Returns

none.

Referenced by CpuUserProgramStartHook().

#### 7.634.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

Referenced by CopInitHook().

#### 7.634.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

Referenced by CopServiceHook().

## 7.635 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for \_template/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.635.1 Detailed Description

LED driver source file.

## 7.635.2 Function Documentation

### 7.635.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Referenced by Applnit(), and Init().

### 7.635.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

Referenced by AppTask(), and main().

## 7.636 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Discovery\_STM32F051\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.636.1 Detailed Description

LED driver source file.

### 7.636.2 Function Documentation

#### 7.636.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.636.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.636.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.637 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_CubeIDE/Prog/App/led.c:

**Macros**

### 7.640.1 Detailed Description

LED driver source file.

### 7.640.2 Function Documentation

#### 7.640.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.640.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.640.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.641 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.641.1 Detailed Description

LED driver source file.

### 7.641.2 Function Documentation

#### 7.641.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.641.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.642 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Discovery\_STM32F051\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.642.1 Detailed Description

LED driver source file.

### 7.642.2 Function Documentation

#### 7.642.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.642.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.642.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.643 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.643.1 Detailed Description

LED driver source file.

### 7.643.2 Function Documentation

#### 7.643.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.643.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.644 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Nucleo\_F091RC\_CubeIDE/Boot/App/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.644.1 Detailed Description

LED driver source file.

### 7.644.2 Function Documentation

#### 7.644.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.644.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.644.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.645 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC00\_STM32F0\_Nucleo\_F091RC\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.645.1 Detailed Description

LED driver source file.

### 7.645.2 Function Documentation

#### 7.645.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.645.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.646 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Nucleo\_F091RC\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Holds the desired LED blink interval time.*

### 7.646.1 Detailed Description

LED driver source file.

### 7.646.2 Function Documentation

#### 7.646.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.646.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.646.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.647 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Nucleo\_F091RC\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.647.1 Detailed Description

LED driver source file.

### 7.647.2 Function Documentation

#### 7.647.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

**Returns**

none.

#### 7.647.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

**Returns**

none.

## 7.648 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Nucleo\_F091RC\_IAR/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.648.1 Detailed Description

LED driver source file.

### 7.648.2 Function Documentation

#### 7.648.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.648.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.648.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.649 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Nucleo\_F091RC\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.649.1 Detailed Description

LED driver source file.

### 7.649.2 Function Documentation

#### 7.649.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.649.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.650 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMC00\_STM32F0\_Nucleo\_F091RC\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Holds the desired LED blink interval time.*

### 7.650.1 Detailed Description

LED driver source file.

### 7.650.2 Function Documentation

#### 7.650.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.650.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.650.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.651 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Nucleo\_F091RC\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

*Holds the desired LED blink interval time.*

### 7.652.1 Detailed Description

LED driver source file.

### 7.652.2 Function Documentation

#### 7.652.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.652.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.652.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.653 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC00\_STM32G0\_Nucleo\_G071RB\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

LED driver source file.

### 7.656.2 Function Documentation

#### 7.656.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.656.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.656.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.657 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32G0\_Nucleo\_G071RB\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.657.1 Detailed Description

LED driver source file.

### 7.657.2 Function Documentation

#### 7.657.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.657.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.658 led.c File Reference

*Holds the desired LED blink interval time.*

### 7.658.1 Detailed Description

LED driver source file.

### 7.658.2 Function Documentation

#### 7.658.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.658.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.658.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.659 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32G0\_Nucleo\_G071RB\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.659.1 Detailed Description

LED driver source file.

### 7.659.2 Function Documentation

#### 7.659.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.659.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.660 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM0\_XMC1\_XMC1400\_Boot\_Kit\_GCC/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.660.1 Detailed Description

LED driver source file.

### 7.660.2 Function Documentation

#### 7.660.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.660.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.660.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.661 led.c File Reference**

LED driver source file.

```
#include "header.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM0\_XMC1\_XMC1400\_Boot\_Kit\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.661.1 Detailed Description

LED driver source file.

### 7.661.2 Function Documentation

#### 7.661.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.661.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.662 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM0\_XMC1\_XMC1400\_Boot\_Kit\_IAR/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.662.1 Detailed Description

LED driver source file.

### 7.662.2 Function Documentation

#### 7.662.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.662.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.662.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

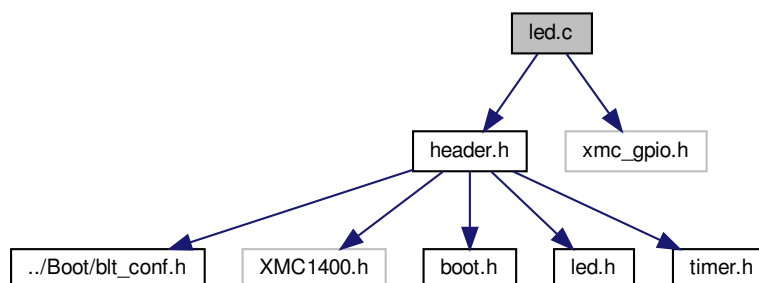

none.

**7.663 led.c File Reference**

LED driver source file.

```
#include "header.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM0\_XMC1\_XMC1400\_Boot\_Kit\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.663.1 Detailed Description

LED driver source file.

### 7.663.2 Function Documentation

#### 7.663.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.663.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.664 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l5xx.h"
#include "stm32l5xx_ll_gpio.h"
```

Include dependency graph for ARMCM33\_STM32L5\_Nucleo\_L552ZE\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.664.1 Detailed Description

LED driver source file.

### 7.664.2 Function Documentation

#### 7.664.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.664.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.664.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.665 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC33\_STM32L5\_Nucleo\_L552ZE\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.665.1 Detailed Description

LED driver source file.

### 7.665.2 Function Documentation

#### 7.665.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.665.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.666 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l5xx.h"
#include "stm32l5xx_ll_gpio.h"
```

Include dependency graph for ARMC33\_STM32L5\_Nucleo\_L552ZE\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

#### 7.679.1 Detailed Description

LED driver source file.

#### 7.679.2 Function Documentation

##### 7.679.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.679.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.680 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

## 7.680.1 Detailed Description

LED driver source file.

## 7.680.2 Function Documentation

### 7.680.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.680.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.680.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.681 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_GCC/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.681.1 Detailed Description

LED driver source file.

### 7.681.2 Function Documentation

#### 7.681.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.681.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.682 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_IAR/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.682.1 Detailed Description

LED driver source file.

### 7.682.2 Function Documentation

#### 7.682.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

##### Returns

none.

#### 7.682.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

#### 7.682.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

##### Returns

none.

## 7.683 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_IAR/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.683.1 Detailed Description

LED driver source file.

### 7.683.2 Function Documentation

#### 7.683.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

Returns

none.

### 7.683.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.684 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

## 7.684.1 Detailed Description

LED driver source file.

## 7.684.2 Function Documentation

### 7.684.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.684.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.684.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.685 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Nucleo\_F103RB\_Keil/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.685.1 Detailed Description

LED driver source file.

### 7.685.2 Function Documentation

#### 7.685.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.685.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.686 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimex\_STM32H103\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.686.1 Detailed Description

LED driver source file.

### 7.686.2 Function Documentation

#### 7.686.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

##### Returns

none.

#### 7.686.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

#### 7.686.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

##### Returns

none.

## 7.687 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimex\_STM32H103\_CubeIDE/Prog/App/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

### 7.688.1 Detailed Description

LED driver source file.

### 7.688.2 Function Documentation

#### 7.688.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.688.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.688.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.689 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC32F1\_Olimex\_STM32H103\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

## 7.689.1 Detailed Description

LED driver source file.

## 7.689.2 Function Documentation

### 7.689.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.689.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

```

Include dependency graph for ARMC3M3\_STM32F1\_Olimex\_STM32P103\_IAR/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.698.1 Detailed Description

LED driver source file.

### 7.698.2 Function Documentation

#### 7.698.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.698.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.698.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.699 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimex\_STM32P103\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

## 7.699.1 Detailed Description

LED driver source file.

## 7.699.2 Function Documentation

### 7.699.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.699.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.700 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMC3M3\_STM32F1\_Olimex\_STM32P103\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.700.1 Detailed Description

LED driver source file.

### 7.700.2 Function Documentation

#### 7.700.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.700.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.700.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.701 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimex\_STM32P103\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.701.1 Detailed Description

LED driver source file.

### 7.701.2 Function Documentation

#### 7.701.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.701.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.702 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMC3M3\_STM32F1\_Olimexino\_STM32\_CubelIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

### 7.702.1 Detailed Description

LED driver source file.

### 7.702.2 Function Documentation

#### 7.702.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.702.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.702.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.703 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC32F1\_Olimexino\_STM32\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.703.1 Detailed Description

LED driver source file.

### 7.703.2 Function Documentation

#### 7.703.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.703.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.704 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

Include dependency graph for ARMC32F1\_Olimexino\_STM32\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)

### 7.704.1 Detailed Description

LED driver source file.

### 7.704.2 Function Documentation

#### 7.704.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.704.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.704.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.705 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimexino\_STM32\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.705.1 Detailed Description

LED driver source file.

### 7.705.2 Function Documentation

#### 7.705.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.705.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.706 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f1xx.h"
#include "stm32f1xx_ll_gpio.h"
```

- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.716.1 Detailed Description

LED driver source file.

### 7.716.2 Function Documentation

#### 7.716.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.716.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.716.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.717 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F2\_Olimex\_STM32P207\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.717.1 Detailed Description

LED driver source file.

### 7.717.2 Function Documentation

#### 7.717.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.717.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.718 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "device_registers.h"
```

Include dependency graph for ARMCM4\_S32K14\_S32K144EVB\_GCC/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.718.1 Detailed Description

LED driver source file.

### 7.718.2 Function Documentation

#### 7.718.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.718.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.718.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.719 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_S32K14\_S32K144EVB\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500U)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.719.1 Detailed Description

LED driver source file.

### 7.719.2 Function Documentation

#### 7.719.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.719.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.720 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "device_registers.h"
Include dependency graph for ARMCM4_S32K14_S32K144EVB_IAR/Boot/led.c:
```

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.720.1 Detailed Description

LED driver source file.

### 7.720.2 Function Documentation

#### 7.720.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.720.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.720.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.721 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_S32K14\_S32K144EVB\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500U)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.721.1 Detailed Description

LED driver source file.

### 7.721.2 Function Documentation

#### 7.721.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

**Returns**

none.

#### 7.721.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

**Returns**

none.

## 7.722 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f3xx.h"
#include "stm32f3xx_ll_gpio.h"
```

Include dependency graph for ARMC4\_STM32F3\_Discovery\_F303VC\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.722.1 Detailed Description

LED driver source file.

### 7.722.2 Function Documentation

#### 7.722.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.722.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.722.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.723 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32F3\_Discovery\_F303VC\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.723.1 Detailed Description

LED driver source file.

### 7.723.2 Function Documentation

#### 7.723.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

#### 7.723.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.724 led.c File Reference

LED driver source file.

```
#include "boot.h"

```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

#### 7.734.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

##### Returns

none.

## 7.735 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32F3\_Nucleo\_F303K8\_IAR/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

#### 7.735.1 Detailed Description

LED driver source file.

#### 7.735.2 Function Documentation

##### 7.735.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

Returns

none.

### 7.735.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.736 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f3xx.h"
#include "stm32f3xx_ll_gpio.h"
```

Include dependency graph for ARMCM4\_STM32F3\_Nucleo\_F303K8\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

## 7.736.1 Detailed Description

LED driver source file.

## 7.736.2 Function Documentation

### 7.736.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.736.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.736.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.737 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32F3\_Nucleo\_F303K8\_Keil/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.737.1 Detailed Description

LED driver source file.

### 7.737.2 Function Documentation

#### 7.737.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.737.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.738 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f4xx.h"
```

Include dependency graph for ARMCM4\_STM32F4\_Nucleo\_F429ZI\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.738.1 Detailed Description

LED driver source file.

### 7.738.2 Function Documentation

#### 7.738.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

##### Returns

none.

#### 7.738.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

#### 7.738.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

##### Returns

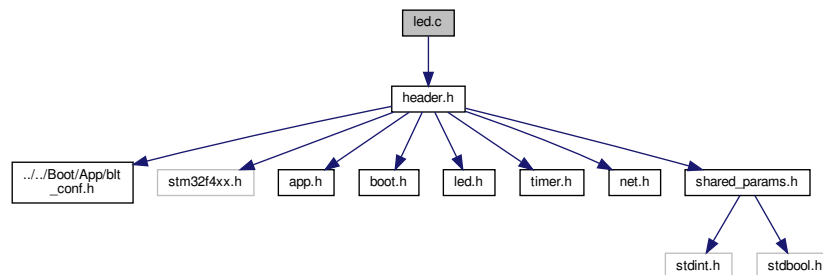

none.

## 7.739 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32F4\_Nucleo\_F429ZI\_CubeIDE/Prog/App/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.739.1 Detailed Description

LED driver source file.

### 7.739.2 Function Documentation

#### 7.739.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

Returns

none.

### 7.739.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

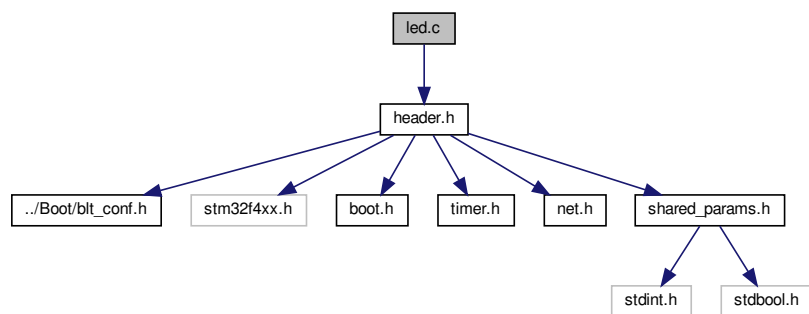

none.

## 7.740 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC4\_STM32F4\_Nucleo\_F429ZI\_GCC/Prog/led.c:

## Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

## Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.740.1 Detailed Description

LED driver source file.

## 7.740.2 Function Documentation

### 7.740.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.740.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

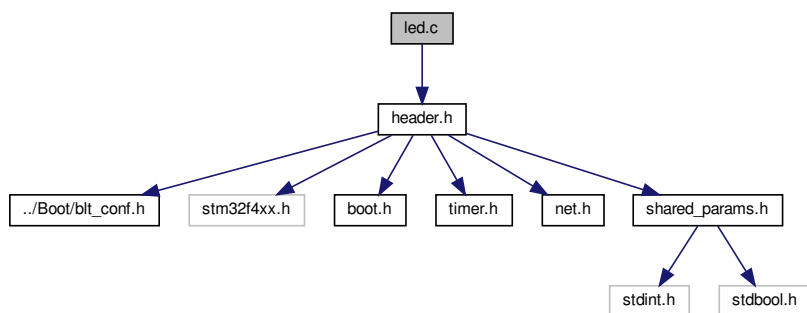

none.

## 7.741 led.c File Reference

LED driver source file.

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.754.1 Detailed Description

LED driver source file.

### 7.754.2 Function Documentation

#### 7.754.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.754.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.755 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l4xx.h"
#include "stm32l4xx_ll_gpio.h"
```

Include dependency graph for ARMCM4\_STM32L4\_Nucleo\_L476RG\_IAR/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

## 7.755.1 Detailed Description

LED driver source file.

## 7.755.2 Function Documentation

### 7.755.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.755.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.755.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.756 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32L4\_Nucleo\_L476RG\_IAR/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.756.1 Detailed Description

LED driver source file.

### 7.756.2 Function Documentation

#### 7.756.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.756.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.757 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32l4xx.h"
#include "stm32l4xx_ll_gpio.h"
```

Include dependency graph for ARMCM4\_STM32L4\_Nucleo\_L476RG\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.757.1 Detailed Description

LED driver source file.

### 7.757.2 Function Documentation

#### 7.757.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

##### Returns

none.

#### 7.757.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

##### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

##### Returns

none.

#### 7.757.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

##### Returns

none.

## 7.758 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_STM32L4\_Nucleo\_L476RG\_Keil/Prog/led.c:

### Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

### Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

## 7.758.1 Detailed Description

LED driver source file.

## 7.758.2 Function Documentation

### 7.758.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.758.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.759 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_TM4C\_DK\_TM4C123G\_IAR/Prog/led.c:

## Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

## Functions

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.759.1 Detailed Description

LED driver source file.

### 7.759.2 Function Documentation

### 7.759.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

### 7.759.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.760 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM4\_XMC4\_XMC4700\_Relax\_Kit\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Holds the desired LED blink interval time.*

### 7.760.1 Detailed Description

LED driver source file.

### 7.760.2 Function Documentation

#### 7.760.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.760.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.760.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.761 led.c File Reference**

LED driver source file.

```
#include "header.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM4\_XMC4\_XMC4700\_Relax\_Kit\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.761.1 Detailed Description

LED driver source file.

### 7.761.2 Function Documentation

#### 7.761.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.761.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.762 led.c File Reference

LED driver source file.

```
#include "boot.h"

*Holds the desired LED blink interval time.*

### 7.762.1 Detailed Description

LED driver source file.

### 7.762.2 Function Documentation

#### 7.762.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.762.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.762.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

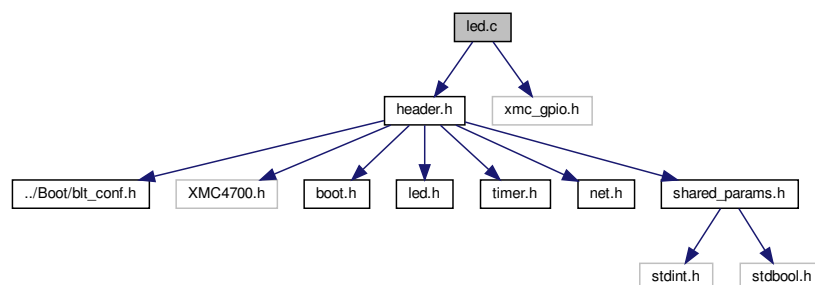

none.

**7.763 led.c File Reference**

LED driver source file.

```
#include "header.h"
#include "xmc_gpio.h"
```

Include dependency graph for ARMCM4\_XMC4\_XMC4700\_Relax\_Kit\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.763.1 Detailed Description

LED driver source file.

### 7.763.2 Function Documentation

#### 7.763.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.763.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.764 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f7xx.h"
#include "stm32f7xx_ll_gpio.h"
```

Include dependency graph for ARMC7\_STM32F7\_Nucleo\_F746ZG\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)

*Holds the desired LED blink interval time.*

### 7.772.1 Detailed Description

LED driver source file.

### 7.772.2 Function Documentation

#### 7.772.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.772.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.772.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.773 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.773.1 Detailed Description

LED driver source file.

### 7.773.2 Function Documentation

#### 7.773.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.773.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.774 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f7xx.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_GCC/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.774.1 Detailed Description

LED driver source file.

### 7.774.2 Function Documentation

#### 7.774.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.774.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.774.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

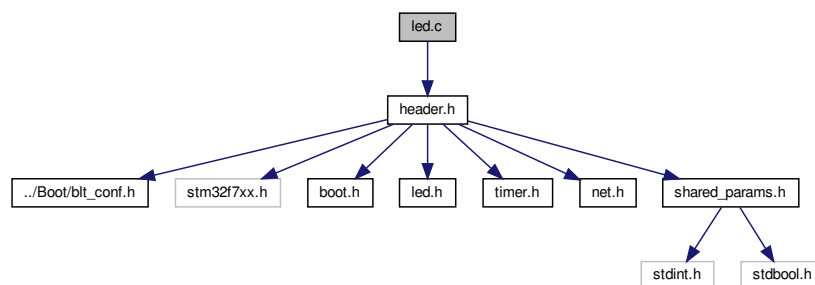

none.

**7.775 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_GCC/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.775.1 Detailed Description

LED driver source file.

### 7.775.2 Function Documentation

#### 7.775.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.775.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.776 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f7xx.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_IAR/Boot/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.776.1 Detailed Description

LED driver source file.

### 7.776.2 Function Documentation

#### 7.776.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.776.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.776.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.777 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC7\_STM32F7\_Nucleo\_F767ZI\_IAR/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.777.1 Detailed Description

LED driver source file.

### 7.777.2 Function Documentation

#### 7.777.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.777.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.778 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32f7xx.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_Keil/Boot/led.c:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static [blt\\_int16u](#) [ledBlinkIntervalMs](#)  
*Holds the desired LED blink interval time.*

### 7.778.1 Detailed Description

LED driver source file.

### 7.778.2 Function Documentation

#### 7.778.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.778.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.778.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.779 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC7\_STM32F7\_Nucleo\_F767ZI\_Keil/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- void `LedInit` (void)  
*Initializes the LED.*
- void `LedToggle` (void)  
*Toggles the LED at a fixed time interval.*

### 7.779.1 Detailed Description

LED driver source file.

### 7.779.2 Function Documentation

#### 7.779.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.779.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.780 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"
#include "stm32h7xx.h"
#include "stm32h7xx_ll_gpio.h"
```

Include dependency graph for ARMCM7\_STM32H7\_Nucleo\_H743ZI\_CubeIDE/Boot/App/led.c:

## Functions

- void `LedBlinkInit` (`blt_int16u` interval\_ms)  
*Initializes the LED blink driver.*
- void `LedBlinkTask` (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void `LedBlinkExit` (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

## Variables

- static `blt_int16u` `ledBlinkIntervalMs`  
*Holds the desired LED blink interval time.*

### 7.780.1 Detailed Description

LED driver source file.

### 7.780.2 Function Documentation

#### 7.780.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.780.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.780.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.781 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for ARMC7\_STM32H7\_Nucleo\_H743ZI\_CubeIDE/Prog/App/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.781.1 Detailed Description

LED driver source file.

### 7.781.2 Function Documentation

#### 7.781.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.781.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.782 led.c File Reference

LED driver source file.

```
#include "boot.h"
#include "led.h"

*Holds the desired LED blink interval time.*

### 7.788.1 Detailed Description

LED driver source file.

### 7.788.2 Function Documentation

#### 7.788.2.1 `LedBlinkExit()`

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.788.2.2 `LedBlinkInit()`

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.788.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.789 led.c File Reference**

LED driver source file.

```
#include "header.h"
```

Include dependency graph for HCS12\_DevKit\_S12G128\_CodeWarrior/Prog/led.c:

**Macros**

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

**Functions**

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.789.1 Detailed Description

LED driver source file.

### 7.789.2 Function Documentation

#### 7.789.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.789.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.790 led.c File Reference

LED driver source file.

```
#include "header.h"
```

Include dependency graph for HCS12\_Evbplus\_Dragon12p\_CodeWarrior/Prog/led.c:

## Macros

- `#define LED_TOGGLE_MS (500)`  
*Toggle interval time in milliseconds.*

## Functions

- `void LedInit (void)`  
*Initializes the LED.*
- `void LedToggle (void)`  
*Toggles the LED at a fixed time interval.*

### 7.790.1 Detailed Description

LED driver source file.

### 7.790.2 Function Documentation

#### 7.790.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

#### 7.790.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.791 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.791.1 Detailed Description

LED driver header file.

### 7.791.2 Function Documentation

#### 7.791.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.791.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

## Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

## Returns

none.

## 7.791.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

## Returns

none.

## 7.792 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

LED driver header file.

### 7.792.2 Function Documentation

#### 7.792.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.792.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.793 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.793.1 Detailed Description

LED driver header file.

### 7.793.2 Function Documentation

#### 7.793.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.793.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.793.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.794 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.794.1 Detailed Description

LED driver header file.

### 7.794.2 Function Documentation

### 7.794.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.794.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.795 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.795.1 Detailed Description

LED driver header file.

### 7.795.2 Function Documentation

#### 7.795.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.795.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.795.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.796 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.796.1 Detailed Description

LED driver header file.

### 7.796.2 Function Documentation

### 7.796.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.796.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.797 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.797.1 Detailed Description

LED driver header file.

### 7.797.2 Function Documentation

#### 7.797.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.797.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.797.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.798 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.798.1 Detailed Description

LED driver header file.

### 7.798.2 Function Documentation

### 7.798.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.798.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.799 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.799.1 Detailed Description

LED driver header file.

### 7.799.2 Function Documentation

#### 7.799.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.799.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.799.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.800 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.800.1 Detailed Description

LED driver header file.

### 7.800.2 Function Documentation

### 7.800.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.800.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.801 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.801.1 Detailed Description

LED driver header file.

### 7.801.2 Function Documentation

#### 7.801.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.801.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.801.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.802 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.802.1 Detailed Description

LED driver header file.

### 7.802.2 Function Documentation

### 7.802.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.802.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.803 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.803.1 Detailed Description

LED driver header file.

### 7.803.2 Function Documentation

#### 7.803.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.803.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.803.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.804 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.804.1 Detailed Description

LED driver header file.

### 7.804.2 Function Documentation

#### 7.804.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.804.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

### 7.805 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.805.1 Detailed Description

LED driver header file.

### 7.805.2 Function Documentation

#### 7.805.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.805.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.805.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.806 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.806.1 Detailed Description

LED driver header file.

### 7.806.2 Function Documentation

### 7.806.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.806.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.807 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.807.1 Detailed Description

LED driver header file.

### 7.807.2 Function Documentation

#### 7.807.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.807.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.807.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.808 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.808.1 Detailed Description

LED driver header file.

### 7.808.2 Function Documentation

### 7.808.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.808.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.809 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.809.1 Detailed Description

LED driver header file.

### 7.809.2 Function Documentation

#### 7.809.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.809.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.809.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.810 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.810.1 Detailed Description

LED driver header file.

### 7.810.2 Function Documentation

### 7.810.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.810.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.811 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.811.1 Detailed Description

LED driver header file.

### 7.811.2 Function Documentation

#### 7.811.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.811.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.811.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.812 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.812.1 Detailed Description

LED driver header file.

### 7.812.2 Function Documentation

### 7.812.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.812.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.813 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.813.1 Detailed Description

LED driver header file.

### 7.813.2 Function Documentation

#### 7.813.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.813.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.813.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.814 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.814.1 Detailed Description

LED driver header file.

### 7.814.2 Function Documentation

#### 7.814.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.814.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.815 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.815.1 Detailed Description

LED driver header file.

### 7.815.2 Function Documentation

#### 7.815.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.815.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.815.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.816 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.816.1 Detailed Description

LED driver header file.

### 7.816.2 Function Documentation

### 7.816.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.816.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.817 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.817.1 Detailed Description

LED driver header file.

### 7.817.2 Function Documentation

#### 7.817.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.817.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.817.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.818 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.818.1 Detailed Description

LED driver header file.

### 7.818.2 Function Documentation

### 7.818.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.818.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.819 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.819.1 Detailed Description

LED driver header file.

### 7.819.2 Function Documentation

#### 7.819.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.819.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.819.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.820 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.820.1 Detailed Description

LED driver header file.

### 7.820.2 Function Documentation

### 7.820.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.820.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.821 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.821.1 Detailed Description

LED driver header file.

### 7.821.2 Function Documentation

#### 7.821.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.821.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.821.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.822 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.822.1 Detailed Description

LED driver header file.

### 7.822.2 Function Documentation

### 7.822.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.822.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.823 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.823.1 Detailed Description

LED driver header file.

### 7.823.2 Function Documentation

#### 7.823.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.823.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.823.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.824 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.824.1 Detailed Description

LED driver header file.

### 7.824.2 Function Documentation

### 7.824.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.824.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.825 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.825.1 Detailed Description

LED driver header file.

### 7.825.2 Function Documentation

#### 7.825.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.825.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.825.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.826 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.826.1 Detailed Description

LED driver header file.

### 7.826.2 Function Documentation

### 7.826.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.826.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.827 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.827.1 Detailed Description

LED driver header file.

### 7.827.2 Function Documentation

#### 7.827.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.827.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.827.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.828 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.828.1 Detailed Description

LED driver header file.

### 7.828.2 Function Documentation

### 7.828.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.828.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.829 led.h File Reference

LED driver header file.

```
#include "lcdcontroller.h"
```

Include dependency graph for ARMCM3\_EFM32\_Olimex\_EM32G880F128STK\_GCC/Prog/led.h:

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.829.1 Detailed Description

LED driver header file.

### 7.829.2 Function Documentation

#### 7.829.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.829.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.830 led.h File Reference

LED driver header file.

```
#include "lcdcontroller.h"
```

Include dependency graph for ARMC32\_EFM32\_Olimex\_EM32G880F128STK\_IAR/Prog/led.h:

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.830.1 Detailed Description

LED driver header file.

### 7.830.2 Function Documentation

#### 7.830.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.830.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.831 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.831.1 Detailed Description

LED driver header file.

### 7.831.2 Function Documentation

#### 7.831.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.831.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.832 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.832.1 Detailed Description

LED driver header file.

### 7.832.2 Function Documentation

### 7.832.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.832.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.833 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.833.1 Detailed Description

LED driver header file.

### 7.833.2 Function Documentation

#### 7.833.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.833.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.834 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.834.1 Detailed Description

LED driver header file.

### 7.834.2 Function Documentation

#### 7.834.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

**Returns**

none.

Initializes the LED.

**Returns**

none.

### 7.834.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.835 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.835.1 Detailed Description

LED driver header file.

### 7.835.2 Function Documentation

### 7.835.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.835.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.835.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.836 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.836.1 Detailed Description

LED driver header file.

### 7.836.2 Function Documentation

#### 7.836.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.836.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.837 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.837.1 Detailed Description

LED driver header file.

### 7.837.2 Function Documentation

### 7.837.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.837.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.837.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.838 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.838.1 Detailed Description

LED driver header file.

### 7.838.2 Function Documentation

#### 7.838.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.838.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.839 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.839.1 Detailed Description

LED driver header file.

### 7.839.2 Function Documentation

### 7.839.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.839.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.839.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.840 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.840.1 Detailed Description

LED driver header file.

### 7.840.2 Function Documentation

#### 7.840.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.840.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.841 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.841.1 Detailed Description

LED driver header file.

### 7.841.2 Function Documentation

### 7.841.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.841.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.841.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.842 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.842.1 Detailed Description

LED driver header file.

### 7.842.2 Function Documentation

#### 7.842.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.842.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.843 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.843.1 Detailed Description

LED driver header file.

### 7.843.2 Function Documentation

### 7.843.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.843.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.843.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.844 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.844.1 Detailed Description

LED driver header file.

### 7.844.2 Function Documentation

#### 7.844.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.844.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.845 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.845.1 Detailed Description

LED driver header file.

### 7.845.2 Function Documentation

### 7.845.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.845.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.845.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.846 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.846.1 Detailed Description

LED driver header file.

### 7.846.2 Function Documentation

#### 7.846.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.846.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.847 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.847.1 Detailed Description

LED driver header file.

### 7.847.2 Function Documentation

### 7.847.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.847.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.847.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.848 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.848.1 Detailed Description

LED driver header file.

### 7.848.2 Function Documentation

#### 7.848.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.848.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.849 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.862.1 Detailed Description

LED driver header file.

### 7.862.2 Function Documentation

#### 7.862.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.862.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.863 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.863.1 Detailed Description

LED driver header file.

### 7.863.2 Function Documentation

### 7.863.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.863.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.863.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.864 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.864.1 Detailed Description

LED driver header file.

### 7.864.2 Function Documentation

#### 7.864.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.864.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.865 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.865.1 Detailed Description

LED driver header file.

### 7.865.2 Function Documentation

### 7.865.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.865.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.865.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.866 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.866.1 Detailed Description

LED driver header file.

### 7.866.2 Function Documentation

#### 7.866.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.866.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.867 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.867.1 Detailed Description

LED driver header file.

### 7.867.2 Function Documentation

### 7.867.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.867.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.867.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.868 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.868.1 Detailed Description

LED driver header file.

### 7.868.2 Function Documentation

#### 7.868.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.868.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.869 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.869.1 Detailed Description

LED driver header file.

### 7.869.2 Function Documentation

### 7.869.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.869.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.869.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.870 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.870.1 Detailed Description

LED driver header file.

### 7.870.2 Function Documentation

#### 7.870.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.870.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.871 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)

- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.885.1 Detailed Description

LED driver header file.

### 7.885.2 Function Documentation

### 7.885.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.885.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.885.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.886 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.886.1 Detailed Description

LED driver header file.

### 7.886.2 Function Documentation

#### 7.886.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.886.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.887 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.887.1 Detailed Description

LED driver header file.

### 7.887.2 Function Documentation

### 7.887.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.887.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.887.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.888 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.888.1 Detailed Description

LED driver header file.

### 7.888.2 Function Documentation

#### 7.888.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.888.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.889 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.889.1 Detailed Description

LED driver header file.

### 7.889.2 Function Documentation

### 7.889.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.889.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.889.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.890 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.890.1 Detailed Description

LED driver header file.

### 7.890.2 Function Documentation

#### 7.890.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.890.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.891 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.891.1 Detailed Description

LED driver header file.

### 7.891.2 Function Documentation

### 7.891.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.891.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.891.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.892 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.892.1 Detailed Description

LED driver header file.

### 7.892.2 Function Documentation

#### 7.892.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.892.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.893 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.893.1 Detailed Description

LED driver header file.

### 7.893.2 Function Documentation

### 7.893.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.893.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.893.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.894 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.894.1 Detailed Description

LED driver header file.

### 7.894.2 Function Documentation

#### 7.894.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.894.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.895 led.h File Reference

LED driver header file.

LED driver header file.

### 7.898.2 Function Documentation

#### 7.898.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.898.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

## Parameters

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

## Returns

none.

## 7.898.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

## Returns

none.

## 7.899 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)

## 7.899.1 Detailed Description

LED driver header file.

## 7.899.2 Function Documentation

### 7.899.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

### 7.899.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.899.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.900 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.900.1 Detailed Description

LED driver header file.

### 7.900.2 Function Documentation

#### 7.900.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.900.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

**Parameters**

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

**Returns**

none.

**7.900.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

**7.901 led.h File Reference**

LED driver header file.

This graph shows which files directly or indirectly include this file:

**Functions**

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.901.1 Detailed Description

LED driver header file.

### 7.901.2 Function Documentation

#### 7.901.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.901.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.902 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.906.1 Detailed Description

LED driver header file.

### 7.906.2 Function Documentation

#### 7.906.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.906.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <a href="#">interval_ms</a> | Specifies the desired LED blink interval time in milliseconds. |
|-----------------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.906.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.907 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.907.1 Detailed Description

LED driver header file.

### 7.907.2 Function Documentation

### 7.907.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.907.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.908 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.908.1 Detailed Description

LED driver header file.

### 7.908.2 Function Documentation

#### 7.908.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.908.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.908.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.909 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.909.1 Detailed Description

LED driver header file.

### 7.909.2 Function Documentation

### 7.909.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.909.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.910 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.910.1 Detailed Description

LED driver header file.

### 7.910.2 Function Documentation

#### 7.910.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.910.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.910.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.911 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.911.1 Detailed Description

LED driver header file.

### 7.911.2 Function Documentation

### 7.911.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.911.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.912 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.912.1 Detailed Description

LED driver header file.

### 7.912.2 Function Documentation

#### 7.912.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.912.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.912.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.913 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.913.1 Detailed Description

LED driver header file.

### 7.913.2 Function Documentation

### 7.913.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.913.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.914 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.914.1 Detailed Description

LED driver header file.

### 7.914.2 Function Documentation

#### 7.914.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.914.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.914.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.915 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.915.1 Detailed Description

LED driver header file.

### 7.915.2 Function Documentation

### 7.915.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.915.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.916 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.916.1 Detailed Description

LED driver header file.

### 7.916.2 Function Documentation

#### 7.916.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.916.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.917 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.917.1 Detailed Description

LED driver header file.

### 7.917.2 Function Documentation

#### 7.917.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.917.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

**Parameters**

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>interval_ms</code> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------------|----------------------------------------------------------------|

**Returns**

none.

**7.917.2.3 LedBlinkTask()**

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

**Returns**

none.

## 7.918 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

**Functions**

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.918.1 Detailed Description

LED driver header file.

### 7.918.2 Function Documentation

#### 7.918.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

#### 7.918.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

## 7.919 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.919.1 Detailed Description

LED driver header file.

### 7.919.2 Function Documentation

#### 7.919.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.919.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.919.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.920 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.920.1 Detailed Description

LED driver header file.

### 7.920.2 Function Documentation

### 7.920.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.920.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.921 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

### 7.921.1 Detailed Description

LED driver header file.

### 7.921.2 Function Documentation

#### 7.921.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.921.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.921.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.922 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.922.1 Detailed Description

LED driver header file.

### 7.922.2 Function Documentation

### 7.922.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.922.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.923 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.923.1 Detailed Description

LED driver header file.

### 7.923.2 Function Documentation

#### 7.923.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.923.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.923.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.924 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.924.1 Detailed Description

LED driver header file.

### 7.924.2 Function Documentation

### 7.924.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.924.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.925 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.929.1 Detailed Description

LED driver header file.

### 7.929.2 Function Documentation

#### 7.929.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.929.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.929.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.930 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.930.1 Detailed Description

LED driver header file.

### 7.930.2 Function Documentation

### 7.930.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.930.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.931 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.931.1 Detailed Description

LED driver header file.

### 7.931.2 Function Documentation

#### 7.931.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.931.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.931.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.932 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

#### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.932.1 Detailed Description

LED driver header file.

### 7.932.2 Function Documentation

### 7.932.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.932.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.933 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.933.1 Detailed Description

LED driver header file.

### 7.933.2 Function Documentation

#### 7.933.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.933.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.933.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.934 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.934.1 Detailed Description

LED driver header file.

### 7.934.2 Function Documentation

### 7.934.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.934.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.935 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.935.1 Detailed Description

LED driver header file.

### 7.935.2 Function Documentation

#### 7.935.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.935.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.935.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.936 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.936.1 Detailed Description

LED driver header file.

### 7.936.2 Function Documentation

### 7.936.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.936.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.937 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.937.1 Detailed Description

LED driver header file.

### 7.937.2 Function Documentation

#### 7.937.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.937.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.937.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.938 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.938.1 Detailed Description

LED driver header file.

### 7.938.2 Function Documentation

### 7.938.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.938.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.939 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.939.1 Detailed Description

LED driver header file.

### 7.939.2 Function Documentation

#### 7.939.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.939.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.939.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.940 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.940.1 Detailed Description

LED driver header file.

### 7.940.2 Function Documentation

### 7.940.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.940.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.941 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.941.1 Detailed Description

LED driver header file.

### 7.941.2 Function Documentation

#### 7.941.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.941.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.941.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.942 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.942.1 Detailed Description

LED driver header file.

### 7.942.2 Function Documentation

### 7.942.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.942.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.943 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*

*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.943.1 Detailed Description

LED driver header file.

### 7.943.2 Function Documentation

#### 7.943.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

#### 7.943.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

### 7.943.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

## 7.944 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

### Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.944.1 Detailed Description

LED driver header file.

### 7.944.2 Function Documentation

### 7.944.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

#### Returns

none.

Initializes the LED.

#### Returns

none.

### 7.944.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

#### Returns

none.

## 7.945 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedBlinkInit](#) ([blt\\_int16u](#) interval\_ms)  
*Initializes the LED blink driver.*
- void [LedBlinkTask](#) (void)  
*Task function for blinking the LED as a fixed timer interval.*
- void [LedBlinkExit](#) (void)  
*Cleans up the LED blink driver. This is intended to be used upon program exit.*

### 7.945.1 Detailed Description

LED driver header file.

### 7.945.2 Function Documentation

#### 7.945.2.1 LedBlinkExit()

```
void LedBlinkExit (
 void)
```

Cleans up the LED blink driver. This is intended to be used upon program exit.

#### Returns

none.

Referenced by [CpuUserProgramStartHook\(\)](#).

#### 7.945.2.2 LedBlinkInit()

```
void LedBlinkInit (
 blt_int16u interval_ms)
```

Initializes the LED blink driver.

#### Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>interval_ms</i> | Specifies the desired LED blink interval time in milliseconds. |
|--------------------|----------------------------------------------------------------|

#### Returns

none.

Referenced by CopInitHook().

### 7.945.2.3 LedBlinkTask()

```
void LedBlinkTask (
 void)
```

Task function for blinking the LED as a fixed timer interval.

#### Returns

none.

Referenced by CopServiceHook().

## 7.946 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.946.1 Detailed Description

LED driver header file.

### 7.946.2 Function Documentation

#### 7.946.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

**Returns**

none.

Initializes the LED.

**Returns**

none.

#### 7.946.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

**Returns**

none.

## 7.947 led.h File Reference

LED driver header file.

This graph shows which files directly or indirectly include this file:

## Functions

- void [LedInit](#) (void)  
*Initializes the LED.*
- void [LedToggle](#) (void)  
*Toggles the LED at a fixed time interval.*

### 7.947.1 Detailed Description

LED driver header file.

### 7.947.2 Function Documentation

#### 7.947.2.1 LedInit()

```
void LedInit (
 void)
```

Initializes the LED.

##### Returns

none.

Initializes the LED.

##### Returns

none.

Referenced by [Applnit\(\)](#), and [Init\(\)](#).

#### 7.947.2.2 LedToggle()

```
void LedToggle (
 void)
```

Toggles the LED at a fixed time interval.

##### Returns

none.

Referenced by [AppTask\(\)](#), and [main\(\)](#).

## 7.948 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
```

Include dependency graph for \_template/Boot/main.c:

### Functions

- static void [Init](#) (void)  
*Initializes the microcontroller.*
- int [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.948.1 Detailed Description

Bootloader application source file.

### 7.948.2 Function Documentation

#### 7.948.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by [main\(\)](#).

### 7.948.2.2 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

## 7.949 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for `_template/Prog/main.c`:

#### Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.949.1 Detailed Description

Demo program application source file.

## 7.949.2 Function Documentation

### 7.949.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.949.2.2 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

## 7.950 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_rcc.h"
#include "stm32f0xx_ll_bus.h"
#include "stm32f0xx_ll_system.h"
#include "stm32f0xx_ll_utils.h"
#include "stm32f0xx_ll_usart.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_GCC/Boot/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.950.1 Detailed Description

Bootloader application source file.

### 7.950.2 Function Documentation

#### 7.950.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.950.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.950.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.950.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.950.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.951 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_GCC/Prog/main.c:

### Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock.*

*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.951.1 Detailed Description

Demo program application source file.

### 7.951.2 Function Documentation

#### 7.951.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.951.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.951.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.951.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program exit code.

## 7.951.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

## Returns

none.

Referenced by Init().

## 7.952 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "stm32f0xx.h"
#include "stm32f0xx_ll_rcc.h"
#include "stm32f0xx_ll_bus.h"
#include "stm32f0xx_ll_system.h"
#include "stm32f0xx_ll_utils.h"
#include "stm32f0xx_ll_usart.h"
#include "stm32f0xx_ll_gpio.h"
```

Include dependency graph for ARMCM0\_STM32F0\_Discovery\_STM32F051\_IAR/Boot/main.c:

## Functions

- static void [Init](#) (void)  
*Initializes the microcontroller.*
- static void [SystemClock\\_Config](#) (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- void [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.952.1 Detailed Description

Bootloader application source file.

### 7.952.2 Function Documentation

#### 7.952.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.952.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.952.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.952.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

#### 7.952.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

## 7.953 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

### 7.953.1 Detailed Description

Demo program application source file.

### 7.953.2 Function Documentation

#### 7.953.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.953.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.953.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.953.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.953.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.954.1 Detailed Description

Bootloader application source file.

### 7.954.2 Function Documentation

#### 7.954.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.954.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.954.2.3 Init()

```
static void Init (
 void) [static]

## 7.955.1 Detailed Description

Demo program application source file.

## 7.955.2 Function Documentation

### 7.955.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.955.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.955.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

#### 7.955.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

#### 7.955.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

##### Returns

none.

Referenced by Init().

Demo program application source file.

### 7.957.2 Function Documentation

#### 7.957.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.957.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.957.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.957.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program exit code.

## 7.957.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

## Returns

none.

Referenced by Init().

## 7.958.1 Detailed Description

Bootloader application source file.

## 7.958.2 Function Documentation

### 7.958.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.958.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.958.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

#### 7.958.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

#### 7.958.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

### 7.959.1 Detailed Description

Demo program application source file.

### 7.959.2 Function Documentation

#### 7.959.2.1 `HAL_MspDeInit()`

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.959.2.2 `HAL_MspInit()`

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.959.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.959.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.959.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.960.1 Detailed Description

Bootloader application source file.

### 7.960.2 Function Documentation

### 7.960.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.960.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.960.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.960.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.960.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

Demo program application source file.

## 7.961.2 Function Documentation

### 7.961.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.961.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.961.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

#### 7.961.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program exit code.

#### 7.961.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

##### Returns

none.

Referenced by Init().

## 7.962 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "stm32g0xx.h"
#include "stm32g0xx_ll_rcc.h"
#include "stm32g0xx_ll_bus.h"
#include "stm32g0xx_ll_system.h"
#include "stm32g0xx_ll_utils.h"
#include "stm32g0xx_ll_gpio.h"
```

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.962.1 Detailed Description

Bootloader application source file.

### 7.962.2 Function Documentation

#### 7.962.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.962.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.962.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.962.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.962.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.963 main.c File Reference

Demo program application source file.

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.973.1 Detailed Description

Demo program application source file.

### 7.973.2 Function Documentation

#### 7.973.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.973.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.973.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.973.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.973.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.973.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

## 7.974 main.c File Reference

Bootloader application source file.

Bootloader application source file.

## 7.974.2 Function Documentation

### 7.974.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.974.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.974.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

#### 7.974.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

#### 7.974.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.990.1 Detailed Description

Bootloader application source file.

### 7.990.2 Function Documentation

#### 7.990.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.990.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.990.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.990.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.990.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.991 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

### Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock.*
- static void `VectorBase_Config` (void)  
*Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function `SystemInit()` overwrites this change again.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.991.1 Detailed Description

Demo program application source file.

### 7.991.2 Function Documentation

#### 7.991.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.991.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.991.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.991.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program return code.

### 7.991.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.991.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.999.1 Detailed Description

Demo program application source file.

### 7.999.2 Function Documentation

### 7.999.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.999.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.999.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.999.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.999.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.999.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

## 7.1000 main.c File Reference

Bootloader application source file.

```
#include "boot.h"

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1000.1 Detailed Description

Bootloader application source file.

### 7.1000.2 Function Documentation

#### 7.1000.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1000.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1000.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1000.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.1000.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.1001 main.c File Reference

Demo program application source file.

### 7.1001.1 Detailed Description

Demo program application source file.

### 7.1001.2 Function Documentation

#### 7.1001.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1001.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1001.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.1001.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program return code.

## 7.1001.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

## Returns

none.

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1008.1 Detailed Description

Bootloader application source file.

### 7.1008.2 Function Documentation

#### 7.1008.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1008.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1008.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1008.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.1008.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.1009 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for ARMCM3\_STM32F1\_Olimexino\_STM32\_GCC/Prog/main.c:

### Functions

- static void [Init](#) (void)  
*Initializes the microcontroller.*
- static void [SystemClock\\_Config](#) (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock.*
- static void [VectorBase\\_Config](#) (void)  
*Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.*
- int [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

*Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.1009.1 Detailed Description

Demo program application source file.

### 7.1009.2 Function Documentation

### 7.1009.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1009.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1009.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1009.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

## 7.1009.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

## Returns

none.

Referenced by Init().

## 7.1009.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

## Returns

none.

Referenced by Init().

 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1017.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1017.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.1017.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

## 7.1017.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

## Returns

none.

Referenced by Init().

## 7.1017.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

## Returns

none.

Referenced by Init().

## 7.1018 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "stm32f2xx.h"
#include "stm32f2xx_ll_rcc.h"
#include "stm32f2xx_ll_bus.h"

### 7.1027.1 Detailed Description

Demo program application source file.

### 7.1027.2 Function Documentation

#### 7.1027.2.1 `HAL_MspDeInit()`

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1027.2.2 `HAL_MspInit()`

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1027.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1027.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.1027.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.1027.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

## 7.1028.1 Detailed Description

Bootloader application source file.

## 7.1028.2 Function Documentation

### 7.1028.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1028.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1028.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

#### 7.1028.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program return code.

#### 7.1028.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

### 7.1029 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for ARMC4\_STM32F3\_Discovery\_F303VC\_Keil/Prog/main.c:

## Functions

### 7.1029.1 Detailed Description

Demo program application source file.

### 7.1029.2 Function Documentation

#### 7.1029.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1029.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

### 7.1029.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1029.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.1029.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

## 7.1029.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

## Returns

none.

Referenced by Init().

### 7.1037.1 Detailed Description

Demo program application source file.

### 7.1037.2 Function Documentation

#### 7.1037.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1037.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

### 7.1037.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1037.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.1037.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

## 7.1037.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

## Returns

none.

Referenced by Init().

## 7.1038 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "stm32f4xx.h"
#include "shared_params.h"
```

Include dependency graph for ARMCM4\_STM32F4\_Nucleo\_F429ZI\_IAR/Boot/main.c:

## Functions

- static void [Init](#) (void)  
*Initializes the microcontroller.*
- static void [SystemClock\\_Config](#) (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- void [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void [HAL\\_MspInit](#) (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1038.1 Detailed Description

Bootloader application source file.

### 7.1038.2 Function Documentation

#### 7.1038.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1038.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1038.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.1038.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

#### 7.1038.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

### 7.1045.1 Detailed Description

Demo program application source file.

### 7.1045.2 Function Documentation

#### 7.1045.2.1 `HAL_MspDeInit()`

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1045.2.2 `HAL_MspInit()`

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from `HAL_Init()` function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

### 7.1045.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1045.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

None.

### 7.1045.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

## 7.1045.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

## Returns

none.

Referenced by Init().

This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- int [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void [HAL\\_MspInit](#) (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1046.1 Detailed Description

Bootloader application source file.

### 7.1046.2 Function Documentation

#### 7.1046.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1046.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

##### Returns

none.

#### 7.1046.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by main().

#### 7.1046.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

Program exit code.

#### 7.1046.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

##### Returns

none.

Referenced by Init().

## 7.1047 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

### 7.1047.1 Detailed Description

Demo program application source file.

### 7.1047.2 Function Documentation

#### 7.1047.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1047.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1047.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1047.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.1047.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.1047.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

## 7.1057.1 Detailed Description

Demo program application source file.

## 7.1057.2 Function Documentation

### 7.1057.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1057.2.2 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

## 7.1058 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
#include "xmc_gpio.h"
#include "xmc_uart.h"
#include "xmc_can.h"
#include "shared_params.h"
```

Include dependency graph for ARMCM4\_XMC4\_XMC4700\_Relax\_Kit\_IAR/Boot/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `PostInit` (void)  
*Post initialization of the microcontroller. Contains all initialization code that should run after the bootloader's core was initialized.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.1058.1 Detailed Description

Bootloader application source file.

### 7.1058.2 Function Documentation

#### 7.1058.2.1 `Init()`

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by `main()`.

#### 7.1058.2.2 `main()`

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

None.

### 7.1058.2.3 PostInit()

```
static void PostInit (
 void) [static]
```

Post initialization of the microcontroller. Contains all initialization code that should run after the bootloader's core was initialized.

#### Returns

none.

Referenced by main().

## 7.1059 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for ARMCM4\_XMC4\_XMC4700\_Relax\_Kit\_IAR/Prog/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- int `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1060.1 Detailed Description

Bootloader application source file.

### 7.1060.2 Function Documentation

#### 7.1060.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1060.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1060.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1060.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program return code.

### 7.1060.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

Referenced by Init().

## 7.1061 main.c File Reference

Demo program application source file.

### 7.1061.1 Detailed Description

Demo program application source file.

### 7.1061.2 Function Documentation

### 7.1061.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1061.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1061.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1061.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.1061.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.1061.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

Include dependency graph for ARMC7\_STM32F7\_Nucleo\_F767ZI\_IAR/Boot/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClock_Config` (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*
- void `HAL_MspInit` (void)  
*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void `HAL_MspDeInit` (void)  
*DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).*

### 7.1068.1 Detailed Description

Bootloader application source file.

### 7.1068.2 Function Documentation

#### 7.1068.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

DeInitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level de-initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

#### 7.1068.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1068.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1068.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

None.

### 7.1068.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock to match the configuration in the bootloader's configuration (blt\_conf.h), specifically the macros: BOOT\_CPU\_SYSTEM\_SPEED\_KHZ and BOOT\_CPU\_XTAL\_SPEED\_KHZ. Note that the Lower Layer drivers were selected in CubeMX for the RCC subsystem.

#### Returns

none.

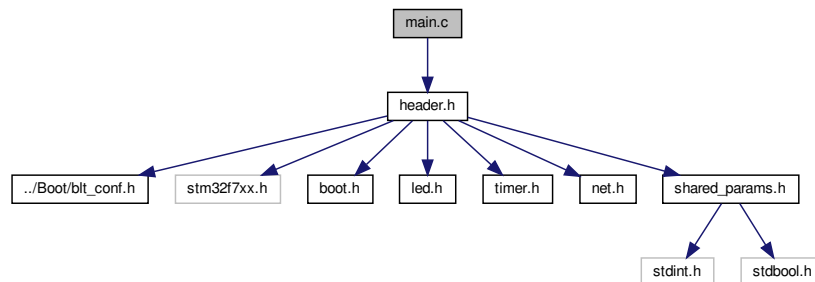

Referenced by Init().

## 7.1069 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for ARMCM7\_STM32F7\_Nucleo\_F767ZI\_IAR/Prog/main.c:

## Functions

- static void [Init](#) (void)  
*Initializes the microcontroller.*
- static void [SystemClock\\_Config](#) (void)  
*System Clock Configuration. This code was created by CubeMX and configures the system clock.*
- static void [VectorBase\\_Config](#) (void)  
*Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.*
- void [main](#) (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

*Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).*
- void [HAL\\_MspDeInit](#) (void)  
*Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.1069.1 Detailed Description

Demo program application source file.

### 7.1069.2 Function Documentation

### 7.1069.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1069.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1069.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1069.2.4 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

None.

### 7.1069.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.1069.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

## 7.1070 main.c File Reference

*Deinitializes the Global MSP. This function is called from `HAL_DeInit()` function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).*

### 7.1077.1 Detailed Description

Demo program application source file.

### 7.1077.2 Function Documentation

### 7.1077.2.1 HAL\_MspDeInit()

```
void HAL_MspDeInit (
 void)
```

Deinitializes the Global MSP. This function is called from HAL\_DeInit() function to perform system level Deinitialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1077.2.2 HAL\_MspInit()

```
void HAL_MspInit (
 void)
```

Initializes the Global MSP. This function is called from HAL\_Init() function to perform system level initialization (GPIOs, clock, DMA, interrupt).

#### Returns

none.

### 7.1077.2.3 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1077.2.4 main()

```
int main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

Program exit code.

### 7.1077.2.5 SystemClock\_Config()

```
static void SystemClock_Config (
 void) [static]
```

System Clock Configuration. This code was created by CubeMX and configures the system clock.

#### Returns

none.

Referenced by Init().

### 7.1077.2.6 VectorBase\_Config()

```
static void VectorBase_Config (
 void) [static]
```

Vector base address configuration. It should no longer be at the start of flash memory but moved forward because the first part of flash is reserved for the bootloader. Note that this is already done by the bootloader before starting this program. Unfortunately, function SystemInit() overwrites this change again.

#### Returns

none.

Referenced by Init().

## 7.1078 main.c File Reference

Demo program application source file.

```
#include <hidef.h>
#include "boot.h"
#include "derivative.h"
```

Include dependency graph for HCS12\_DevKit\_S12G128\_CodeWarrior/Boot/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClockInit` (void)  
*Initializes the clock configuration of the microcontroller.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.1078.1 Detailed Description

Demo program application source file.

### 7.1078.2 Function Documentation

#### 7.1078.2.1 `Init()`

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

##### Returns

none.

Referenced by `main()`.

#### 7.1078.2.2 `main()`

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

##### Returns

none.

### 7.1078.2.3 SystemClockInit()

```
static void SystemClockInit (
 void) [static]
```

Initializes the clock configuration of the microcontroller.

#### Returns

none.

Referenced by Init().

## 7.1079 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for HCS12\_DevKit\_S12G128\_CodeWarrior/Prog/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SystemClockInit` (void)  
*Initializes the clock configuration of the microcontroller.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.1079.1 Detailed Description

Demo program application source file.

## 7.1079.2 Function Documentation

### 7.1079.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1079.2.2 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.1079.2.3 SystemClockInit()

```
static void SystemClockInit (
 void) [static]
```

Initializes the clock configuration of the microcontroller.

#### Returns

none.

Referenced by Init().

## 7.1080 main.c File Reference

Bootloader application source file.

```
#include "boot.h"
```

```
#include "derivative.h"
```

Include dependency graph for HCS12\_Evbplus\_Dragon12p\_CodeWarrior/Boot/main.c:

### Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

### 7.1080.1 Detailed Description

Bootloader application source file.

### 7.1080.2 Function Documentation

#### 7.1080.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by `main()`.

## 7.1080.2.2 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

## Returns

none.

## 7.1081 main.c File Reference

Demo program application source file.

```
#include "header.h"
```

Include dependency graph for HCS12\_Evbplus\_Dragon12p\_CodeWarrior/Prog/main.c:

## Functions

- static void `Init` (void)  
*Initializes the microcontroller.*
- static void `SysClockInit` (void)  
*Initializes the microcontroller.*
- void `main` (void)  
*This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.*

## 7.1081.1 Detailed Description

Demo program application source file.

## 7.1081.2 Function Documentation

### 7.1081.2.1 Init()

```
static void Init (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by main().

### 7.1081.2.2 main()

```
void main (
 void)
```

This is the entry point for the bootloader application and is called by the reset interrupt vector after the C-startup routines executed.

#### Returns

none.

### 7.1081.2.3 SysClockInit()

```
static void SysClockInit (
 void) [static]
```

Initializes the microcontroller.

#### Returns

none.

Referenced by Init().

## 7.1082.2 Function Documentation

### 7.1082.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

#### Returns

none.

### 7.1082.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

#### Returns

none.

Referenced by AppInit(), ComInit(), and main().

### 7.1082.2.3 NetTask()

```
void NetTask (
 void)
```

Runs the TCP/IP server task.

#### Returns

none.

Referenced by AppTask(), and main().

## 7.1083 net.c File Reference

Network application for the uIP TCP/IP stack.

```
#include "header.h"
#include "netdev.h"
#include "uip.h"
#include "uip_arp.h"
```

Include dependency graph for Demo/ARMCM3\_LM3S\_EK\_LM3S6965\_IAR/Prog/net.c:

### Macros

- `#define NET_UIP_PERIODIC_TIMER_MS (500)`  
*Delta time for the uIP periodic timer.*
- `#define NET_UIP_ARP_TIMER_MS (10000)`  
*Delta time for the uIP ARP timer.*
- `#define NET_UIP_HEADER_BUF ((struct uip_eth_hdr *)&uip_buf[0])`  
*Macro for accessing the Ethernet header information in the buffer.*

### Functions

- void `NetInit` (void)  
*Initializes the TCP/IP network communication interface.*
- void `NetApp` (void)  
*The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.*
- void `NetTask` (void)  
*Runs the TCP/IP server task.*

### Variables

- static unsigned long `periodicTimerTimeout`  
*Holds the time out value of the uIP periodic timer.*
- static unsigned long `ARPTimerTimeout`  
*Holds the time out value of the uIP ARP timer.*
- static struct uip\_eth\_addr `macAddress`  
*Holds the MAC address which is used by the DHCP client.*

#### 7.1083.1 Detailed Description

Network application for the uIP TCP/IP stack.

## 7.1083.2 Function Documentation

### 7.1083.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

#### Returns

none.

### 7.1083.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

#### Returns

none.

### 7.1083.2.3 NetTask()

```
void NetTask (
 void)
```

Runs the TCP/IP server task.

#### Returns

none.

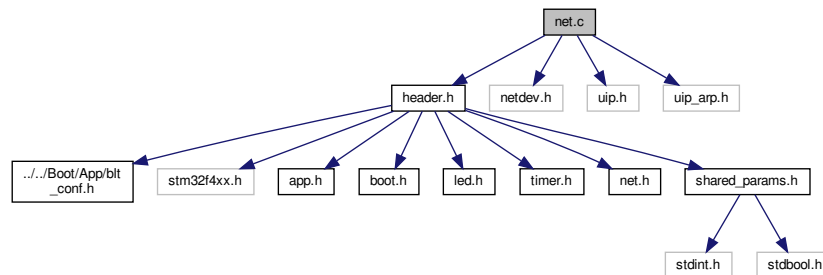

## 7.1084 net.c File Reference

Network application for the uIP TCP/IP stack.

```
#include "header.h"
#include "netdev.h"
#include "uip.h"

- `#define NET_UIP_PERIODIC_TIMER_MS (500)`  
*Delta time for the uIP periodic timer.*
- `#define NET_UIP_ARP_TIMER_MS (10000)`  
*Delta time for the uIP ARP timer.*
- `#define NET_UIP_HEADER_BUF ((struct uip_eth_hdr *)&uip_buf[0])`  
*Macro for accessing the Ethernet header information in the buffer.*

### Functions

- void `NetInit` (void)  
*Initializes the TCP/IP network communication interface.*
- void `NetApp` (void)  
*The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.*
- void `NetTask` (void)  
*Runs the TCP/IP server task.*

### Variables

- static unsigned long `periodicTimerTimeOut`  
*Holds the time out value of the uIP periodic timer.*
- static unsigned long `ARPTimerTimeOut`  
*Holds the time out value of the uIP ARP timer.*
- static struct uip\_eth\_addr `macAddress`  
*Holds the MAC address which is used by the DHCP client.*

### 7.1092.1 Detailed Description

Network application for the uIP TCP/IP stack.

### 7.1092.2 Function Documentation

#### 7.1092.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

##### Returns

none.

#### 7.1092.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

##### Returns

none.

#### 7.1092.2.3 NetTask()

```
void NetTask (
 void)
```

Runs the TCP/IP server task.

##### Returns

none.

## 7.1093 net.c File Reference

Network application for the uIP TCP/IP stack.

```
#include "header.h"
#include "netdev.h"
#include "uip.h"
#include "uip_arp.h"
```

Include dependency graph for Demo/ARMCM7\_STM32F7\_Nucleo\_F767ZI\_Keil/Prog/net.c:

### Macros

- `#define NET_UIP_PERIODIC_TIMER_MS (500)`  
*Delta time for the uIP periodic timer.*
- `#define NET_UIP_ARP_TIMER_MS (10000)`  
*Delta time for the uIP ARP timer.*
- `#define NET_UIP_HEADER_BUF ((struct uip_eth_hdr *)&uip_buf[0])`  
*Macro for accessing the Ethernet header information in the buffer.*

### Functions

### 7.1093.1 Detailed Description

Network application for the uIP TCP/IP stack.

### 7.1093.2 Function Documentation

#### 7.1093.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

##### Returns

none.

#### 7.1093.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

##### Returns

none.

#### 7.1093.2.3 NetTask()

```
void NetTask (
 void)
```

Runs the TCP/IP server task.

##### Returns

none.

## 7.1094 net.c File Reference

Bootloader TCP/IP network communication interface source file.

```
#include "boot.h"
#include "netdev.h"
#include "uip.h"
#include "uip_arp.h"
```

Include dependency graph for Source/net.c:

### Macros

- `#define NET_UIP_PERIODIC_TIMER_MS (500)`  
*Delta time for the uIP periodic timer.*
- `#define NET_UIP_ARP_TIMER_MS (10000)`  
*Delta time for the uIP ARP timer.*
- `#define NET_UIP_HEADER_BUF ((struct uip_eth_hdr *)&uip_buf[0])`  
*Macro for accessing the Ethernet header information in the buffer.*

### Functions

*Runs the TCP/IP server task.*
- void `NetInit` (void)  
*Initializes the TCP/IP network communication interface.*
- void `NetTransmitPacket` (blt\_int8u \*data, blt\_int8u len)  
*Transmits a packet formatted for the communication interface.*
- blt\_bool `NetReceivePacket` (blt\_int8u \*data, blt\_int8u \*len)  
*Receives a communication interface packet if one is present.*
- void `NetApp` (void)  
*The uIP network application that implements XCP on TCP/IP. Note that this application make use of the fact that XCP is request/response based. So no new request will come in when a response is pending for transmission, if so, the transmission of the pending response is aborted.*

### Variables

- static blt\_int32u `periodicTimerTimeOut`  
*Holds the time out value of the uIP periodic timer.*
- static blt\_int32u `ARPTimerTimeOut`  
*Holds the time out value of the uIP ARP timer.*
- static blt\_bool `netInitializedFlag = BLT_FALSE`  
*Boolean flag to determine if the module was initialized or not.*
- static blt\_bool `netInitializationDeferred = BLT_FALSE`  
*Boolean flag initialized such that the normal initialization via `NetInit()` proceeds as usual.*

### 7.1094.1 Detailed Description

Bootloader TCP/IP network communication interface source file.

### 7.1094.2 Function Documentation

#### 7.1094.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that implements XCP on TCP/IP. Note that this application make use of the fact that XCP is request/response based. So no new request will come in when a response is pending for transmission, if so, the transmission of the pending response is aborted.

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

#### Returns

none.

#### 7.1094.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

#### Returns

none.

#### 7.1094.2.3 NetReceivePacket()

```
blt_bool NetReceivePacket (
 blt_int8u * data,
 blt_int8u * len)
```

Receives a communication interface packet if one is present.

**Parameters**

|             |                                                         |
|-------------|---------------------------------------------------------|
| <i>data</i> | Pointer to byte array where the data is to be stored.   |
| <i>len</i>  | Pointer where the length of the packet is to be stored. |

**Returns**

BLT\_TRUE if a packet was received, BLT\_FALSE otherwise.

Referenced by ComTask().

**7.1094.2.4 NetServerTask()**

```
static void NetServerTask (
 void) [static]
```

Runs the TCP/IP server task.

**Returns**

none.

Referenced by NetReceivePacket().

**7.1094.2.5 NetTransmitPacket()**

```
void NetTransmitPacket (
 blt_int8u * data,
 blt_int8u len)
```

Transmits a packet formatted for the communication interface.

**Parameters**

|             |                                                            |
|-------------|------------------------------------------------------------|
| <i>data</i> | Pointer to byte array with data that it to be transmitted. |
| <i>len</i>  | Number of bytes that are to be transmitted.                |

**Returns**

none.

Referenced by ComTransmitPacket().

## 7.1095 net.h File Reference

Network application for the uIP TCP/IP stack.

This graph shows which files directly or indirectly include this file:

### Data Structures

- struct [uip\\_tcp\\_appstate\\_t](#)

Define the [uip\\_tcp\\_appstate\\_t](#) datatype. This is the state of our tcp/ip application, and the memory required for this state is allocated together with each TCP connection. One application state for each TCP connection.

### Functions

- void [NetInit](#) (void)  
*Initializes the TCP/IP network communication interface.*
- void [NetApp](#) (void)  
*The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.*

### 7.1106.2.3 NetTask()

```
void NetTask (
 void)
```

Runs the TCP/IP server task.

#### Returns

none.

Referenced by AppTask(), and main().

## 7.1107 net.h File Reference

Bootloader TCP/IP network communication interface header file.

This graph shows which files directly or indirectly include this file:

### Data Structures

- struct [uiptcp\\_appstate\\_t](#)

Define the [uiptcp\\_appstate\\_t](#) datatype. This is the state of our tcp/ip application, and the memory required for this state is allocated together with each TCP connection. One application state for each TCP connection.

### Functions

- void [NetInit](#) (void)  
*Initializes the TCP/IP network communication interface.*
- void [NetApp](#) (void)  
*The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.*
- void [NetTransmitPacket](#) (blt\_int8u \*data, blt\_int8u len)  
*Transmits a packet formatted for the communication interface.*
- blt\_bool [NetReceivePacket](#) (blt\_int8u \*data, blt\_int8u \*len)  
*Receives a communication interface packet if one is present.*

### 7.1107.1 Detailed Description

Bootloader TCP/IP network communication interface header file.

### 7.1107.2 Function Documentation

### 7.1107.2.1 NetApp()

```
void NetApp (
 void)
```

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

#### Returns

none.

The uIP network application that detects the XCP connect command on the port used by the bootloader. This indicates that the bootloader should be activated.

#### Returns

none.

### 7.1107.2.2 NetInit()

```
void NetInit (
 void)
```

Initializes the TCP/IP network communication interface.

#### Returns

none.

Referenced by ApplInit(), ComInit(), and main().

### 7.1107.2.3 NetReceivePacket()

```
blt_bool NetReceivePacket (
 blt_int8u * data,
 blt_int8u * len)
```

Receives a communication interface packet if one is present.

#### Parameters

|             |                                                         |
|-------------|---------------------------------------------------------|
| <i>data</i> | Pointer to byte array where the data is to be stored.   |
| <i>len</i>  | Pointer where the length of the packet is to be stored. |

**Returns**

BLT\_TRUE if a packet was received, BLT\_FALSE otherwise.

Referenced by ComTask().

**7.1107.2.4 NetTransmitPacket()**

```
void NetTransmitPacket (
 blt_int8u * data,
 blt_int8u len)
```

Transmits a packet formatted for the communication interface.

**Parameters**

|             |                                                            |
|-------------|------------------------------------------------------------|
| <i>data</i> | Pointer to byte array with data that it to be transmitted. |
| <i>len</i>  | Number of bytes that are to be transmitted.                |

**Returns**

none.

Referenced by ComTransmitPacket().

**7.1108 nvm.c File Reference**

Bootloader non-volatile memory driver source file.

```
#include "boot.h"
```

```
#include "flash.h"
```

Include dependency graph for \_template/nvm.c:

## Functions

- void [NvmInitHook](#) (void)  
*Callback that gets called at the start of the internal NVM driver initialization routine.*
- void [NvmReinitHook](#) (void)  
*Callback that gets called at the start of a firmware update to reinitialize the NVM driver.*
- [blt\\_int8u NvmWriteHook](#) ([blt\\_addr](#) addr, [blt\\_int32u](#) len, [blt\\_int8u](#) \*data)  
*Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.*

*Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.*
- [blt\\_bool NvmDone](#) (void)  
*Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.*

### 7.1108.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1108.2 Function Documentation

### 7.1108.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), and XcpCmdProgram().

### 7.1108.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

### 7.1108.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), and XcpCmdProgramClear().

#### 7.1108.2.4 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

##### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

##### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the erase operation failed.

Referenced by NvmErase().

#### 7.1108.2.5 NvmGetUserProgBaseAddress()

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

##### Returns

Base address.

Referenced by CpuStartUserProgram().

#### 7.1108.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

Referenced by BootInit(), FileTask(), and XcpCmdConnect().

### 7.1108.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

Referenced by NvmInit().

### 7.1108.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

#### Returns

none.

### 7.1108.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

Referenced by NvmReinit().

### 7.1108.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by CpuStartUserProgram().

### 7.1108.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), XcpCmdProgram(), and XcpCmdProgramMax().

### 7.1108.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

## Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1109 nvm.c File Reference

## 7.1109.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1109.2 Function Documentation

### 7.1109.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1109.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

### 7.1109.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1109.2.4 NvmEraseHook()

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1109.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

**7.1109.2.6 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

**7.1109.2.7 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

Referenced by NvmInit().

#### 7.1109.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1109.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1109.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1109.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

## Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

## 7.1109.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

## Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1110.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1110.2 Function Documentation

### 7.1110.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1110.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

### 7.1110.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1110.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1110.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1110.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1110.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1110.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1110.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

### 7.1110.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1110.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1110.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1111.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1111.2 Function Documentation

#### 7.1111.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1111.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1111.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1111.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1111.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1111.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1111.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1111.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1111.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

### 7.1111.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1111.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1111.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1112 nvm.c File Reference

### 7.1112.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1112.2 Function Documentation

#### 7.1112.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1112.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1112.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1112.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1112.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1112.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1112.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1112.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1112.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1112.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1112.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1112.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1113.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1113.2 Function Documentation

#### 7.1113.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1113.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

#### 7.1113.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1113.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1113.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1113.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1113.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1113.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1113.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

### 7.1113.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1113.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1113.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1114.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1114.2 Function Documentation

#### 7.1114.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1114.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1114.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1114.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1114.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1114.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1114.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1114.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1114.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1114.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1114.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1114.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1115.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1115.2 Function Documentation

#### 7.1115.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1115.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

#### 7.1115.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1115.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1115.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1115.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1115.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1115.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1115.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

### 7.1115.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1115.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1115.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1116.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1116.2 Function Documentation

### 7.1116.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1116.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

### 7.1116.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1116.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1116.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

### 7.1116.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

#### Returns

none.

### 7.1116.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

Referenced by NvmInit().

### 7.1116.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

#### Returns

none.

### 7.1116.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

Referenced by NvmReinit().

#### 7.1116.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1116.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1116.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1117.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1117.2 Function Documentation

### 7.1117.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1117.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

### 7.1117.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1117.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1117.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

**7.1117.2.6 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

**7.1117.2.7 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

Referenced by NvmInit().

**7.1117.2.8 NvmReinit()**

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

**Returns**

none.

**7.1117.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

Referenced by NvmReinit().

### 7.1117.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1117.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1117.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1118 nvm.c File Reference

Bootloader non-volatile memory driver source file.

### 7.1118.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1118.2 Function Documentation

#### 7.1118.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1118.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1118.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1118.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1118.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1118.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1118.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1118.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1118.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1118.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1118.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1118.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1119 nvm.c File Reference

## 7.1119.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1119.2 Function Documentation

### 7.1119.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1119.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

### 7.1119.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1119.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1119.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

**7.1119.2.6 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

**7.1119.2.7 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

Referenced by NvmInit().

**7.1119.2.8 NvmReinit()**

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

**Returns**

none.

**7.1119.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

Referenced by NvmReinit().

### 7.1119.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1119.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1119.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1120.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1120.2 Function Documentation

#### 7.1120.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1120.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1120.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1120.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1120.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1120.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1120.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1120.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1120.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1120.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1120.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1120.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1121.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1121.2 Function Documentation

#### 7.1121.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1121.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

#### 7.1121.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1121.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1121.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1121.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1121.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1121.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1121.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

### 7.1121.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1121.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1121.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1122 nvm.c File Reference

### 7.1122.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1122.2 Function Documentation

#### 7.1122.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1122.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1122.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1122.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1122.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1122.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1122.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1122.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1122.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1122.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1122.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1122.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1123.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1123.2 Function Documentation

#### 7.1123.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1123.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1123.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1123.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1123.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

**7.1123.2.6 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

**7.1123.2.7 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

Referenced by NvmInit().

**7.1123.2.8 NvmReinit()**

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

**Returns**

none.

**7.1123.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

Referenced by NvmReinit().

### 7.1123.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1123.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1123.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1124 nvm.c File Reference

- Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.*

### 7.1124.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1124.2 Function Documentation

#### 7.1124.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1124.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

#### 7.1124.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1124.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1124.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

#### 7.1124.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

##### Returns

none.

#### 7.1124.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

##### Returns

none.

Referenced by NvmInit().

#### 7.1124.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

##### Returns

none.

#### 7.1124.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

##### Returns

none.

Referenced by NvmReinit().

#### 7.1124.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1124.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1124.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1125.1 Detailed Description

Bootloader non-volatile memory driver source file.

### 7.1125.2 Function Documentation

#### 7.1125.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1125.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

##### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by NvmDone().

#### 7.1125.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1125.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1125.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

**7.1125.2.6 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

**7.1125.2.7 NvmInitHook()**

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

**Returns**

none.

Referenced by NvmInit().

**7.1125.2.8 NvmReinit()**

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

**Returns**

none.

**7.1125.2.9 NvmReinitHook()**

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

**Returns**

none.

Referenced by NvmReinit().

### 7.1125.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1125.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1125.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

#### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

## Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

## 7.1126 nvm.c File Reference

## 7.1126.1 Detailed Description

Bootloader non-volatile memory driver source file.

## 7.1126.2 Function Documentation

### 7.1126.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

### 7.1126.2.2 NvmDoneHook()

```
blt_bool NvmDoneHook (
 void)
```

Callback that gets called at the end of the NVM programming session.

#### Returns

BLT\_TRUE is successful, BLT\_FALSE otherwise.

Referenced by [NvmDone\(\)](#).

### 7.1126.2.3 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

**7.1126.2.4 NvmEraseHook()**

```
blt_int8u NvmEraseHook (
 blt_addr addr,
 blt_int32u len)
```

Callback that gets called at the start of the NVM driver erase routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the memory hasn't been erased yet.

**Parameters**

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

**Returns**

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR is the erase operation failed.

Referenced by NvmErase().

**7.1126.2.5 NvmGetUserProgBaseAddress()**

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

### 7.1126.2.6 NvmInit()

```
void NvmInit (
 void)
```

Initializes the NVM driver.

#### Returns

none.

### 7.1126.2.7 NvmInitHook()

```
void NvmInitHook (
 void)
```

Callback that gets called at the start of the internal NVM driver initialization routine.

#### Returns

none.

Referenced by NvmInit().

### 7.1126.2.8 NvmReinit()

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

#### Returns

none.

### 7.1126.2.9 NvmReinitHook()

```
void NvmReinitHook (
 void)
```

Callback that gets called at the start of a firmware update to reinitialize the NVM driver.

#### Returns

none.

Referenced by NvmReinit().

#### 7.1126.2.10 NvmVerifyChecksum()

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1126.2.11 NvmWrite()

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

##### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

#### 7.1126.2.12 NvmWriteHook()

```
blt_int8u NvmWriteHook (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Callback that gets called at the start of the NVM driver write routine. It allows additional memory to be operated on. If the address is not within the range of the additional memory, then BLT\_NVM\_NOT\_IN\_RANGE must be returned to indicate that the data hasn't been written yet.

##### Parameters

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

### Returns

BLT\_NVM\_OKAY if successful, BLT\_NVM\_NOT\_IN\_RANGE if the address is not within the supported memory range, or BLT\_NVM\_ERROR if the write operation failed.

Referenced by NvmWrite().

### 7.1127.1 Detailed Description

Bootloader non-volatile memory driver header file.

## 7.1127.2 Function Documentation

### 7.1127.2.1 NvmDone()

```
blt_bool NvmDone (
 void)
```

Once all erase and programming operations are completed, this function is called, so at the end of the programming session and right before a software reset is performed. It is used to calculate a checksum and program this into flash. This checksum is later used to determine if a valid user program is present in flash.

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), and XcpCmdProgram().

### 7.1127.2.2 NvmErase()

```
blt_bool NvmErase (
 blt_addr addr,
 blt_int32u len)
```

Erases the non-volatile memory.

#### Parameters

|             |                  |
|-------------|------------------|
| <i>addr</i> | Start address.   |
| <i>len</i>  | Length in bytes. |

#### Returns

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), and XcpCmdProgramClear().

### 7.1127.2.3 NvmGetUserProgBaseAddress()

```
blt_addr NvmGetUserProgBaseAddress (
 void)
```

Obtains the base address of the non-volatile memory available to the user program. This is typically that start of the vector table.

**Returns**

Base address.

Referenced by CpuStartUserProgram().

**7.1127.2.4 NvmInit()**

```
void NvmInit (
 void)
```

Initializes the NVM driver.

**Returns**

none.

Referenced by BootInit(), FileTask(), and XcpCmdConnect().

**7.1127.2.5 NvmReinit()**

```
void NvmReinit (
 void)
```

Reinitializes the NVM driver. This function is called at the start of each firmware update as opposed to NvmInit, which is only called once during power on.

**Returns**

none.

**7.1127.2.6 NvmVerifyChecksum()**

```
blt_bool NvmVerifyChecksum (
 void)
```

Verifies the checksum, which indicates that a valid user program is present and can be started.

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by CpuStartUserProgram().

**7.1127.2.7 NvmWrite()**

```
blt_bool NvmWrite (
 blt_addr addr,
 blt_int32u len,
 blt_int8u * data)
```

Programs the non-volatile memory.

**Parameters**

|             |                             |
|-------------|-----------------------------|
| <i>addr</i> | Start address.              |
| <i>len</i>  | Length in bytes.            |
| <i>data</i> | Pointer to the data buffer. |

**Returns**

BLT\_TRUE if successful, BLT\_FALSE otherwise.

Referenced by FileTask(), XcpCmdProgram(), and XcpCmdProgramMax().

*Reads a data byte from the shared parameter buffer at the specified index.*
- bool `SharedParamsWriteByIndex` (uint32\_t idx, uint8\_t value)  
*Writes a data byte to the shared parameter buffer at the specified index.*

### 7.1147.1 Detailed Description

Shared RAM parameters source file.

### 7.1147.2 Function Documentation

#### 7.1147.2.1 `__attribute__`()

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

### 7.1147.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

## Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1147.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

## Returns

none.

Referenced by AppInit(), and main().

### 7.1147.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

Referenced by ApplInit(), and main().

**7.1147.2.5 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1147.2.6 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1147.2.7 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

### Returns

True if successful, false otherwise.

Referenced by ApplInit(), main(), and NetApp().

#### 7.1147.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1148 shared\_params.c File Reference

### 7.1148.1 Detailed Description

Shared RAM parameters source file.

### 7.1148.2 Function Documentation

7.1148.2.1 `__attribute__()`

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

## Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

7.1148.2.2 `SharedParamsCalculateChecksum()`

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

## Returns

The calculated checksum value.

Referenced by `SharedParamsVerifyChecksum()`, and `SharedParamsWriteChecksum()`.

### 7.1148.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1148.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1148.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

### 7.1148.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

#### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

### 7.1148.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

#### Returns

True if successful, false otherwise.

### 7.1148.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1149 shared\_params.c File Reference

Shared RAM parameters source file.

### 7.1149.1 Detailed Description

Shared RAM parameters source file.

### 7.1149.2 Function Documentation

#### 7.1149.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1149.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

#### 7.1149.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1149.2.4 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1149.2.5 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1149.2.6 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

## Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

## Returns

True if successful, false otherwise.

## 7.1149.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

## Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1149.3 Variable Documentation

## 7.1149.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

## Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

## 7.1150 shared\_params.c File Reference

### 7.1150.1 Detailed Description

Shared RAM parameters source file.

### 7.1150.2 Function Documentation

#### 7.1150.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1150.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

#### 7.1150.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1150.2.4 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1150.2.5 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1150.2.6 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

## Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

## Returns

True if successful, false otherwise.

## 7.1150.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

## Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1150.3 Variable Documentation

## 7.1150.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

## Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. ### 7.1151.1 Detailed Description

Shared RAM parameters source file.

### 7.1151.2 Function Documentation

#### 7.1151.2.1 \_\_attribute\_\_()

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function [main\(\)](#) is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE↔
EP*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. #### 7.1151.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

##### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1151.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

##### Returns

none.

#### 7.1151.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

##### Returns

True if successful, false otherwise.

### 7.1151.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

### 7.1151.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

#### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

### 7.1151.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

#### Returns

True if successful, false otherwise.

### 7.1151.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1152 shared\_params.c File Reference

### 7.1152.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

## Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1152.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

## Returns

none.

### 7.1152.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1152.2.5 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1152.2.6 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1152.2.7 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

### Returns

True if successful, false otherwise.

#### 7.1152.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1153 shared\_params.c File Reference

Shared RAM parameters source file.

```
#include <stddef.h>
#include "shared_params.h"

- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

#### 7.1153.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1153.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1153.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1153.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1153.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1153.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

#### 7.1153.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

##### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1154 shared\_params.c File Reference

Shared RAM parameters source file.

```

### 7.1154.1 Detailed Description

Shared RAM parameters source file.

### 7.1154.2 Function Documentation

#### 7.1154.2.1 `__attribute__()`

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function [main\(\)](#) is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE↔
EP*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

### 7.1154.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1154.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1154.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

#### 7.1154.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

##### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1154.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1154.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

### 7.1154.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1155 shared\_params.c File Reference

### 7.1155.1 Detailed Description

Shared RAM parameters source file.

### 7.1155.2 Function Documentation

#### 7.1155.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by [SharedParamsVerifyChecksum\(\)](#), and [SharedParamsWriteChecksum\(\)](#).

### 7.1155.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1155.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1155.2.4 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1155.2.5 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1155.2.6 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

#### 7.1155.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

##### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

### 7.1155.3 Variable Documentation

#### 7.1155.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

### 7.1156.1 Detailed Description

Shared RAM parameters source file.

### 7.1156.2 Function Documentation

#### 7.1156.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1156.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

#### 7.1156.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1156.2.4 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1156.2.5 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1156.2.6 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

## Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

## Returns

True if successful, false otherwise.

## 7.1156.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

## Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1156.3 Variable Documentation

## 7.1156.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

## Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. *Writes a data byte to the shared parameter buffer at the specified index.*

### 7.1157.1 Detailed Description

Shared RAM parameters source file.

### 7.1157.2 Function Documentation

#### 7.1157.2.1 \_\_attribute\_\_((section("shared"), zero\_init)) static

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__((
 (section("shared"), zero_init))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

### 7.1157.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1157.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1157.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1157.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

### 7.1157.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

#### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

### 7.1157.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

#### Returns

True if successful, false otherwise.

### 7.1157.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1158 shared\_params.c File Reference

### 7.1158.1 Detailed Description

Shared RAM parameters source file.

### 7.1158.2 Function Documentation

#### 7.1158.2.1 `__attribute__`()

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section("shared"), zero_init)) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

### 7.1158.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

## Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1158.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

## Returns

none.

### 7.1158.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1158.2.5 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1158.2.6 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1158.2.7 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

**Returns**

True if successful, false otherwise.

**7.1158.2.8 SharedParamsWriteChecksum()**

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

**Returns**

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

**7.1159 shared\_params.c File Reference**

Shared RAM parameters source file.

```
#include <stddef.h>
```

### 7.1159.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by `SharedParamsVerifyChecksum()`, and `SharedParamsWriteChecksum()`.

### 7.1159.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1159.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1159.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

### 7.1159.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

#### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

### 7.1159.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

#### Returns

True if successful, false otherwise.

### 7.1159.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

### 7.1160.1 Detailed Description

Shared RAM parameters source file.

### 7.1160.2 Function Documentation

#### 7.1160.2.1 `__attribute__()`

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function [main\(\)](#) is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE↔
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. ### 7.1160.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1160.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1160.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

#### 7.1160.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

##### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1160.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1160.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

## 7.1160.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

## Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1161 shared\_params.c File Reference

Shared RAM parameters source file.

```
#include <stddef.h>
#include "shared_params.h"

### 7.1161.1 Detailed Description

Shared RAM parameters source file.

### 7.1161.2 Function Documentation

#### 7.1161.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by [SharedParamsVerifyChecksum\(\)](#), and [SharedParamsWriteChecksum\(\)](#).

### 7.1161.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1161.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1161.2.4 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1161.2.5 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1161.2.6 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

#### 7.1161.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

##### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

### 7.1161.3 Variable Documentation

#### 7.1161.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.(shared))) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

### 7.1162.1 Detailed Description

Shared RAM parameters source file.

### 7.1162.2 Function Documentation

#### 7.1162.2.1 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1162.2.2 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

#### 7.1162.2.3 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1162.2.4 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1162.2.5 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1162.2.6 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

## Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

## Returns

True if successful, false otherwise.

## 7.1162.2.7 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

## Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1162.3 Variable Documentation

## 7.1162.3.1 shared

```
__no_init tSharedParamsBuffer sharedParamsBuffer shared [static]
```

Declaration of the actual parameter buffer that this module manages.

## Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

### 7.1163.1 Detailed Description

Shared RAM parameters source file.

### 7.1163.2 Function Documentation

#### 7.1163.2.1 \_\_attribute\_\_()

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function [main\(\)](#) is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE↔
EP*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

#### Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. - Keil MDK: <http://www.keil.com/support/docs/3480.htm>

#### 7.1163.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

##### Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

#### 7.1163.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

##### Returns

none.

#### 7.1163.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

##### Returns

True if successful, false otherwise.

### 7.1163.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

### 7.1163.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

#### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

### 7.1163.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

#### Returns

True if successful, false otherwise.

### 7.1163.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

#### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

*Reads a data byte from the shared parameter buffer at the specified index.*
- bool `SharedParamsWriteByIndex` (uint32\_t idx, uint8\_t value)  
*Writes a data byte to the shared parameter buffer at the specified index.*

### 7.1164.1 Detailed Description

Shared RAM parameters source file.

### 7.1164.2 Function Documentation

#### 7.1164.2.1 `__attribute__()`

```
static tSharedParamsBuffer sharedParamsBuffer __attribute__ (
 (section(".shared"))) [static]
```

Declaration of the actual parameter buffer that this module manages.

#### Warning

For the shared RAM parameters to work properly for sharing information between the bootloader and user program, it is important that this variable is linked to the exact same RAM address in both the bootloader and the user program. Additionally, it should be configured such that the C-startup code does NOT zero its contents during system initialization. This is the code that runs in the reset event handler, before function `main()` is called. For GCC based embedded toolchains, the solution is to assign this variable to a custom section, in this case called ".shared". Then in the linker script, add the following to the SECTIONS:

```
.shared (NOLOAD) : { . = ALIGN(4); _sshared = .; shared_start = _sshared; *(.shared) *(.shared.*) KE←
EP(*(.shared)) . = ALIGN(4); _eshared = .; shared_end = _eshared; } >SHARED
```

Next, add a new MEMORY entry for SHARED at the start of RAM and reduce the length of the remaining RAM:

```
SHARED (xrw) : ORIGIN = 0x200000C0, LENGTH = 64 RAM (xrw) : ORIGIN = 0x20000100, LENGTH = 32K - 192
- 64
```

Note that the previous example is for an STM32F0 microcontroller where the first 192 (0xC0) bytes in RAM are reserved for the user program vector table.

## Remarks

This same approach can be applied with other toolchains such as Keil MDK and IAR EWARM. Consult the compiler and linker user manuals of your toolchain to find out how to place a RAM variable at a fixed memory address and to prevent the C-startup code from zeroing its contents. Here are a few links to get you started:

- IAR EWARM: <https://www.iar.com/support/tech-notes/compiler/linker-error-for-absolute-located-variable/>
- Keil MDK: <http://www.keil.com/support/docs/3480.htm>

### 7.1164.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

## Returns

The calculated checksum value.

Referenced by SharedParamsVerifyChecksum(), and SharedParamsWriteChecksum().

### 7.1164.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

## Returns

none.

### 7.1164.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

**Returns**

True if successful, false otherwise.

**7.1164.2.5 SharedParamsValidateBuffer()**

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

**Returns**

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

**7.1164.2.6 SharedParamsVerifyChecksum()**

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

**Returns**

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

**7.1164.2.7 SharedParamsWriteByIndex()**

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

**Parameters**

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

**Returns**

True if successful, false otherwise.

**7.1164.2.8 SharedParamsWriteChecksum()**

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

**Returns**

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

**7.1165 shared\_params.c File Reference**

Shared RAM parameters source file.

```
#include <stddef.h>
```

```
#include "shared_params.h"

### 7.1165.2.2 SharedParamsCalculateChecksum()

```
static uint16_t SharedParamsCalculateChecksum (
 void) [static]
```

Calculates and returns the checksum value for the current contents in the buffer. The checksum is calculated by taking the sum of all bytes in the parameter buffer (excluding the checksum at the end) and then taking the two's complement value of it.

#### Returns

The calculated checksum value.

Referenced by `SharedParamsVerifyChecksum()`, and `SharedParamsWriteChecksum()`.

### 7.1165.2.3 SharedParamsInit()

```
void SharedParamsInit (
 void)
```

Initializes the shared RAM parameters module.

#### Returns

none.

### 7.1165.2.4 SharedParamsReadByIndex()

```
bool SharedParamsReadByIndex (
 uint32_t idx,
 uint8_t * value)
```

Reads a data byte from the shared parameter buffer at the specified index.

#### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Pointer to where the read data value is stored.                                                              |

#### Returns

True if successful, false otherwise.

### 7.1165.2.5 SharedParamsValidateBuffer()

```
static bool SharedParamsValidateBuffer (
 void) [static]
```

Validates the shared parameter buffer contents by looking at the table identifier and verifying its checksum.

#### Returns

True if successful, false otherwise.

Referenced by SharedParamsInit(), SharedParamsReadByIndex(), and SharedParamsWriteByIndex().

#### 7.1165.2.6 SharedParamsVerifyChecksum()

```
static bool SharedParamsVerifyChecksum (
 void) [static]
```

Calculates and verifies the checksum that is currently present in the buffer.

##### Returns

True is the checksum is correct, false otherwise.

Referenced by SharedParamsValidateBuffer().

#### 7.1165.2.7 SharedParamsWriteByIndex()

```
bool SharedParamsWriteByIndex (
 uint32_t idx,
 uint8_t value)
```

Writes a data byte to the shared parameter buffer at the specified index.

##### Parameters

|              |                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------|
| <i>idx</i>   | Index into the parameter data array. A valid value is between 0 and (SHARED_PARAMS_CFG_BUFFER_DATA_LEN - 1). |
| <i>value</i> | Value to write.                                                                                              |

##### Returns

True if successful, false otherwise.

#### 7.1165.2.8 SharedParamsWriteChecksum()

```
static void SharedParamsWriteChecksum (
 void) [static]
```

Calculates and writes the checksum into the buffer.

##### Returns

none.

Referenced by SharedParamsInit(), and SharedParamsWriteByIndex().

## 7.1166 shared\_params.c File Reference
